Schur multipliers were introduced by Schur in the early 20th century and have since then found a considerable number of applications in Analysis and enjoyed an intensive development. Apart from the beauty of the subject in itself, sources of interest in them were connections with Perturbation Theory, Harmonic Analysis, the Theory of Operator Integrals and others. Advances in the quantisation of Schur multipliers were recently made in [29]. The aim of the present article is to summarise a part of the ideas and results in the theory of Schur and operator multipliers. We start with the classical Schur multipliers defined by Schur and their characterisation by Grothendieck, and make our way through measurable multipliers studied by Peller and Spronk, operator multipliers defined by Kissin and Shulman and, finally, multidimensional Schur and operator multipliers developed by Juschenko and the authors. We point out connections of the area with Harmonic Analysis and the Theory of Operator Integrals.

1. Classical Schur multipliers

For a Hilbert space $H$, let $\mathcal{B}(H)$ be the collection of all bounded linear operators acting on $H$ equipped with its operator norm $\| \cdot \|_{\text{op}}$. We denote by $\ell^2$ the Hilbert space of all square summable complex sequences. With an operator $A \in \mathcal{B}(\ell^2)$, one can associate a matrix $(a_{i,j})_{i,j\in\mathbb{N}}$ by letting $a_{i,j} = (Ae_j, e_i)$, where $\{e_i\}_{i\in\mathbb{N}}$ is the standard orthonormal basis of $\ell^2$. The space $M_\infty$ of all matrices obtained in this way is a subspace of the space $M_{\mathbb{N}}$ of all complex matrices indexed by $\mathbb{N} \times \mathbb{N}$. It is easy to see that the correspondence between $\mathcal{B}(\ell^2)$ and $M_\infty$ is one-to-one.

Any function $\varphi : \mathbb{N} \times \mathbb{N} \to \mathbb{C}$ gives rise to a linear transformation $S_\varphi$ acting on $M_{\mathbb{N}}$ and given by $S_\varphi((a_{i,j})_{i,j}) = (\varphi(i,j)a_{i,j})_{i,j}$. In other words, $S_\varphi((a_{i,j})_{i,j})$ is the entry-wise product of the matrices $(\varphi(i,j))_{i,j}$ and $(a_{i,j})_{i,j}$, often called Schur product. The function $\varphi$ is called a Schur multiplier if $S_\varphi$ leaves the subspace $M_\infty$ invariant. We denote by $S(\mathbb{N}, \mathbb{N})$ the set of all Schur multipliers.

Let $\varphi$ be a Schur multiplier. Then the correspondence between $\mathcal{B}(\ell^2)$ and $M_\infty$ gives rise to a mapping (which we denote in the same way) on $\mathcal{B}(\ell^2)$. We first note that $S_\varphi$ is necessarily bounded in the operator norm. This follows from the Closed Graph Theorem; indeed, suppose that $A_k \to 0$.

and \( S_\varphi(A_k) \rightarrow B \) in the operator norm, for some elements \( A_k, B \in \mathcal{B}(\ell^2) \), \( k \in \mathbb{N} \). Letting \((a_{i,j}^k)\) and \((b_{i,j})\) be the corresponding matrices of \( A_k \) and \( B \), we have that \( a_{i,j}^k = (A_k e_j, e_i) \rightarrow_{k \rightarrow \infty} 0 \), for each \( i,j \in \mathbb{N} \). But then \( \{\varphi(i,j) a_{i,j}^k\}_{k \in \mathbb{N}} \) converges to both \( b_{i,j} \) and 0, and since this holds for every \( i,j \in \mathbb{N} \), we conclude that \( B = 0 \). Let \( \|\varphi\|_m \) denote the norm of \( S_\varphi \) as a bounded operator on \( \mathcal{B}(\ell^2) \); we call \( \|\varphi\|_m \) the multiplier norm of \( \varphi \).

It now follows that \( S(\mathbb{N}, \mathbb{N}) \subseteq \ell^\infty(\mathbb{N} \times \mathbb{N}) \). Indeed, if \( \{E_{i,j}\}_{i,j \in \mathbb{N}} \) is the canonical matrix unit system in \( \mathcal{B}(\ell^2) \) then we have that \( \|\varphi(i,j)\| = \|S_\varphi(E_{i,j})\|_{\text{op}} \leq \|\varphi\|_m \), for all \( i,j \in \mathbb{N} \). It is trivial to verify that \( S(\mathbb{N}, \mathbb{N}) \) is a subalgebra of \( \ell^\infty(\mathbb{N} \times \mathbb{N}) \) when the latter is equipped with the usual pointwise operations; moreover, it can be shown that \( S(\mathbb{N}, \mathbb{N}) \) is a semi-simple commutative Banach algebra when equipped with the norm \( \| \cdot \|_m \).

We note in passing that, since \( \varphi \) is a bounded function, the restriction of \( S_\varphi \) to the class \( \mathcal{C}_2(\ell^2) \) of all Hilbert-Schmidt operators is bounded when \( \mathcal{C}_2(\ell^2) \) is equipped with its Hilbert-Schmidt norm \( \| \cdot \|_2 \), and its norm as an operator on \( \mathcal{C}_2(\ell^2) \) is equal to \( \|\varphi\|_\infty \). This follows from the fact that if \( A \in \mathcal{C}_2(\ell^2) \) and \((a_{i,j})_{i,j} \in M_\infty \) is the matrix corresponding to \( A \) then \( \|A\|_2 = \left(\sum_{i,j} |a_{i,j}|^2\right)^{\frac{1}{2}} \).

Another immediate observation is the fact that if \((a_{i,j})_{i,j} \in M_\infty \) and \( a \in \ell^\infty(\mathbb{N} \times \mathbb{N}) \) is the function given by \( a(i,j) = a_{i,j} \), then \( a \) is a Schur multiplier and \( \|a\|_m \leq \|a\|_{\text{op}} \). To see this, let \( b \in M_\infty \) and \( B \in \mathcal{B}(\ell^2) \) be the operator corresponding to \( b \). If \( A \in \mathcal{B}(\ell^2) \) is the operator corresponding to \( a \), we have by general operator theory that the norm of the operator \( A \otimes B \in \mathcal{B}(\ell^2 \otimes \ell^2) \) is equal to \( \|A\|_{\text{op}} \|B\|_{\text{op}} \). Identifying \( \ell^2 \otimes \ell^2 \) with \( \ell^2(\mathbb{N} \times \mathbb{N}) \), and letting \( P \in \mathcal{B}(\ell^2 \otimes \ell^2) \) be the projection on the closed linear span of \( \{e_i \otimes e_j\}_{i,j \in \mathbb{N}} \), we see that the matrix \((a_{i,j} b_{i,j})_{i,j} \) corresponds to the operator \( P(A \otimes B)P \). Thus, \( \|S_a(B)\|_{\text{op}} = \|P(A \otimes B)P\|_{\text{op}} \leq \|A\|_{\text{op}} \|B\|_{\text{op}} \), and the claim follows. In fact, \( M_\infty \), equipped with the multiplier norm \( \| \cdot \|_m \) is a (commutative) semi-simple Banach subalgebra of \( S(\mathbb{N}, \mathbb{N}) \).

We summarise the above inclusions:

\[ M_\infty \subseteq S(\mathbb{N}, \mathbb{N}) \subseteq \ell^\infty(\mathbb{N} \times \mathbb{N}) \]

Both of them are strict: for the first one, take the constant function \( 1 \) taking the value 1 on \( \mathbb{N} \times \mathbb{N} \). Obviously, \( 1 \) is a Schur multiplier (in fact, \( S_1 \) is the identity transformation) but does not belong to \( M_\infty \) since the rows and columns of the matrices in \( M_\infty \) are square summable. The fact that the second inclusion is strict is much more subtle. An example of a function which belongs to \( \ell^\infty(\mathbb{N} \times \mathbb{N}) \) but not to \( S(\mathbb{N}, \mathbb{N}) \) is the characteristic function \( \chi_\Delta \) of the set \( \Delta = \{(i,j) : j \leq i\} \), see for example [12].

The question that arises is: “which” functions are Schur multipliers? The following description was obtained by Grothendieck [20]:

**Theorem 1.1.** Let \( \varphi \in \ell^\infty(\mathbb{N} \times \mathbb{N}) \). The following are equivalent:

(i) \( \varphi \) is a Schur multiplier and \( \|\varphi\|_m < C \);
(ii) There exist families \( \{a_k\}_{k \in \mathbb{N}}, \{b_k\}_{k \in \mathbb{N}} \in \ell^\infty \) such that
\[
\sup_{i \in \mathbb{N}} \sum_{k=1}^{\infty} |a_k(i)|^2 < C, \quad \sup_{j \in \mathbb{N}} \sum_{k=1}^{\infty} |b_k(j)|^2 < C
\]
and
\[
\varphi(i, j) = \sum_{k=1}^{\infty} a_k(i)b_k(j), \quad \text{for all } i, j \in \mathbb{N}.
\]
Suppose that we are given two finite families \( \{a_k\}_{k=1}^{N}, \{b_k\}_{k=1}^{N} \subseteq \ell^\infty \) and let \( \varphi \in \ell^\infty(\mathbb{N} \times \mathbb{N}) \) be the function given by \( \varphi(i, j) = \sum_{k=1}^{N} a_k(i)b_k(j) \). For \( a \in \ell^\infty \), let \( D_a \in B(\ell^2) \) be the operator whose matrix has the sequence \( a \) down its main diagonal and zeros everywhere else. An easy computation shows that \( \varphi \) is a Schur multiplier and that, in fact,
\[
S_{\varphi}(T) = \sum_{k=1}^{N} D_{a_k}TD_{b_k}, \quad T \in B(\ell^2).
\]
The transformations on \( B(\ell^2) \) obtained in this way belong to the important class of elementary operators. The norm of this operator, and hence \( \|\varphi\|_m \), is bounded by \( (\sup_{i \in \mathbb{N}} \sum_{k=1}^{N} |a_k(i)|^2 \sup_{j \in \mathbb{N}} \sum_{k=1}^{N} |b_k(j)|^2)^{1/2} \). In fact, for \( f, g \in \ell^2 \)
\[
(1) \quad |(S_{\varphi}(T)f, g)| = \left| \left( \sum_{k=1}^{N} D_{a_k}TD_{b_k}f, g \right) \right| \leq \sum_{k=1}^{N} |(TD_{b_k}f, D_{a_k}^*g)|
\]
\[
\leq \sum_{k=1}^{N} \|TD_{b_k}f\|\|D_{a_k}^*g\|
\]
\[
\leq \left( \sum_{k=1}^{N} \|T\|^2\|D_{b_k}f\|^2 \right)^{1/2} \left( \sum_{k=1}^{N} \|D_{a_k}^*g\|^2 \right)^{1/2}
\]
\[
= \|T\| \left( \sum_{k=1}^{N} D_{b_k}^*D_{b_k}f, f \right)^{1/2} \left( \sum_{k=1}^{N} D_{a_k}D_{a_k}^*g, g \right)^{1/2}
\]
\[
\leq \|T\| \left( \sum_{k=1}^{N} D_{b_k}^*D_{b_k} \right)^{1/2} \left( \sum_{k=1}^{N} D_{a_k}D_{a_k}^* \right)^{1/2} \|f\|\|g\|
\]
which proves the claim.

If \( \varphi \) is an arbitrary Schur multiplier and \( \{a_k\}_{k \in \mathbb{N}} \) and \( \{b_k\}_{k \in \mathbb{N}} \) are the families arising in Grothendieck’s description, then letting \( \varphi_N \) be the function given by \( \varphi_N(i, j) = \sum_{k=1}^{N} a_k(i)b_k(j) \), \( N \in \mathbb{N} \), we have that \( \varphi_N \to \varphi \) pointwise and, moreover (by Grothendieck’s theorem again), the norms \( \|\varphi_N\|_m \) are uniformly bounded in \( N \). Thus, Grothendieck’s characterisation can be viewed as a uniform approximation result for Schur multipliers by “elementary Schur multipliers”. 
There is another convenient formulation of Theorem 1.1 which links the subject of Schur multipliers to Operator Space Theory. Namely, the space of Schur multipliers can be identified with the extended Haagerup tensor product $l_\infty \otimes_{eh} l_\infty$. For the time being, let us take this statement as the definition of the space $l_\infty \otimes_{eh} l_\infty$; more on this will be said later.

Truncation of matrices has been important in applications. Suppose that we are given a matrix — either of finite size, or an element of $M_\infty$. To truncate it along a certain subset $\kappa \subseteq N \times N$ means to replace it by the matrix that has the same entries on the subset $\kappa$ and zeros everywhere else. Obviously, this is precisely the operation of Schur-multiplying a matrix $a \in M_\infty$ by $\chi_\kappa$. Thus, truncation along $\kappa$ is a well-defined (and automatically bounded) transformation on $B(l_2)$ if and only if $\chi_\kappa$ is a Schur multiplier.

The Schur multipliers of this form are precisely the idempotent elements of the Banach algebra $S(N,N)$. It is easy to exhibit idempotent Schur multipliers: if $\{\alpha_k\}_{k=1}^\infty$ and $\{\beta_k\}_{k=1}^\infty$ are families of pairwise disjoint subsets of $N$ and $\kappa = \cup_{k=1}^\infty \alpha_k \times \beta_k$ then

$$S_{\chi_\kappa}(T) = \sum_{k=1}^\infty P_k T Q_k, \quad T \in B(l_2),$$

where $P_k$ (resp. $Q_k$) is the projection onto the closed span of $\{e_i : i \in \alpha_k\}$ (resp. $\{e_i : i \in \beta_k\}$), and hence $\|\chi_\kappa\|_{\text{in}} \leq 1$. Since $S(N,N)$ is an algebra with respect to pointwise multiplication, the function $\chi_\kappa$ is a Schur multiplier for every set $\kappa$ belonging to the subset ring generated by the sets of the above form. It is natural to ask whether the elements of this algebra are all idempotent Schur multipliers. Although the answer to this question is not known (in fact, the question is one of the difficult open problems in the area), a related result was recently established by Davidson and Donsig [13].

Let us call a subset $\kappa \subseteq N \times N$ a Schur bounded pattern if every function $\varphi \in l_\infty(N \times N)$ supported on $\kappa$ is a Schur multiplier. Obviously, if $\kappa$ is a Schur bounded pattern then $\chi_\kappa$ is a Schur multiplier, and not vice versa (just take $\kappa = N \times N$). The aforementioned theorem reads as follows:

**Theorem 1.2.** Let $\kappa \subseteq N \times N$. The following are equivalent:
(i) $\kappa$ is a Schur bounded pattern;
(ii) there exist sets $\kappa_r, \kappa_c \subseteq N \times N$ and a number $N \in \mathbb{N}$ such that $\kappa_r$ (resp. $\kappa_c$) has at most $N$ entries in every row (resp. column) and $\kappa = \kappa_r \cup \kappa_c$.

In fact, the Davidson and Donsig results cover the more general case of non-negative functions $\varphi \in l_\infty(N \times N)$ which are “hereditary Schur multipliers” (the terminology is ours) in the sense that if $\psi \in l_\infty(N \times N)$ and $|\psi| \leq \varphi$ then $\psi$ is a Schur multiplier.

Once there is a complete characterisation of Schur multipliers, it is natural to ask for a description of certain special classes of Schur multipliers. Say that a Schur multiplier $\varphi$ is compact if the mapping $S_\varphi : B(l_2) \to B(l_2)$ is a compact operator. The following result was established by Hladnik in [24]:
Theorem 1.3. A Schur multiplier \( \varphi \in \ell^\infty(\mathbb{N} \times \mathbb{N}) \) is compact if and only if a representation can be chosen for \( \varphi \) as in Theorem 1.1 (ii), such that \( \{a_k\}_{k \in \mathbb{N}}, \{b_k\}_{k \in \mathbb{N}} \subseteq c_0 \) and the series \( \sum_{k=1}^\infty |a_k|^2 \) and \( \sum_{k=1}^\infty |b_k|^2 \) are uniformly convergent.

Positivity is another natural property that a Schur multiplier may (or may not) have: a Schur multiplier \( \varphi \) is called positive if \( S_\varphi(A) \) is a positive operator for every positive operator \( A \). The following holds:

Theorem 1.4. A Schur multiplier \( \varphi \in \ell^\infty(\mathbb{N} \times \mathbb{N}) \) is positive if and only if there exists \( \{a_k\}_{k \in \mathbb{N}} \subseteq \ell^\infty \) such that \( \sup_{i \in \mathbb{N}} \sum_{k=1}^\infty |a_k(i)|^2 < \infty \) and \( \varphi(i, j) = \sum_{k=1}^\infty a_k(i)\bar{a}_k(j) \), for all \( i, j \in \mathbb{N} \).

2. Schur multipliers over measure spaces

If \( \varphi \in \ell^\infty(\mathbb{N} \times \mathbb{N}) \) then the operator on the Hilbert space \( \ell^2(\mathbb{N} \times \mathbb{N}) \) of multiplication by \( \varphi \) is bounded. If we equip \( \ell^2(\mathbb{N} \times \mathbb{N}) \) with the norm arising from its identification with the space \( C_0(\ell^2) \) of all Hilbert-Schmidt operators on \( \ell^2 \), then it is easy to see that \( \varphi \) is a Schur multiplier if and only if this multiplication operator is bounded in the operator norm. This approach is useful because it allows us to study Schur multipliers in a more general setting. To describe this setting, let \( (X, \mu) \) and \( (Y, \nu) \) be standard \( \sigma \)-finite measure spaces. We equip \( X \times Y \) with the product measure \( \mu \times \nu \). The space \( L^2(X \times Y) \) can be canonically identified with the space \( C_0(L^2(X), L^2(Y)) \) of all Hilbert-Schmidt operators from \( L^2(X) \) into \( L^2(Y) \): if \( f \in L^2(X \times Y), \) let \( T_f \) be the Hilbert-Schmidt operator given by

\[
T_f \xi(y) = \int_X f(x, y) \xi(x) d\mu(x), \quad \xi \in L^2(X).
\]

For \( f \in L^2(X \times Y) \), let \( \|f\|_{op} \) be the operator norm of \( T_f \).

Now let \( \varphi \in L^\infty(X \times Y) \). The operator \( S_\varphi : L^2(X \times Y) \to L^2(X \times Y) \) of multiplication by \( \varphi \) is bounded in the \( L^2 \)-norm (its norm is equal to \( \|\varphi\|_{\infty} \)). If \( S_\varphi \) is moreover bounded in \( \| \cdot \|_{op} \), that is, if there exists \( C > 0 \) such that \( \|S_\varphi f\|_{op} \leq C\|f\|_{op} \) for every \( f \in L^2(X \times Y) \), then we call \( \varphi \) a Schur \( \mu, \nu \)-multiplier (or simply a Schur multiplier if the measures are clear from the context).

If \( X = Y = \mathbb{N} \) is equipped with the counting measure, this new notion reduces to the one described in the previous section.

We note that the property of a function \( \varphi \) to be or not to be a Schur multiplier depends only on the values of the function up to a null with respect to the product measure set.

If \( \varphi \in L^\infty(X \times Y) \) is a Schur multiplier then the mapping \( S_\varphi \) extends by continuity to a mapping on \( K(L^2(X), L^2(Y)) \); after taking its second dual we arrive at a bounded weak* continuous linear transformation (which we denote in the same way) on \( B(L^2(X), L^2(Y)) \). The multiplier norm \( \|\varphi\|_{in} \) of \( \varphi \) is defined as the operator norm of \( S_\varphi \). We denote by \( S(X, Y) \) the set of all Schur multipliers. Clearly, \( S(X, Y) \) is a subalgebra of \( L^\infty(X \times Y) \) (with respect to pointwise multiplication).
Let \( D_1 \) (resp. \( D_2 \)) be the multiplicative masa of \( L^\infty(X) \) (resp. \( L^\infty(Y) \)). We denote by \( M_a \) the element of \( D_1 \) corresponding to the element \( a \in L^\infty(X) \); we use a similar notation for the operators in \( D_2 \). If \( f \in L^2(X \times Y) \), \( a \in L^\infty(X) \) and \( b \in L^\infty(Y) \), then \( M_b T_f M_a = T_f(a \otimes b) \), where \( (a \otimes b)(x, y) = a(x)b(y) \), \( x \in X \), \( y \in Y \). It follows that \( S_\varphi \) is a \( D_2, D_1 \)-bimodule map in the sense that \( S_\varphi(BTA) = BS_\varphi(T)A \), for all \( T \in \mathcal{B}(L^2(X), L^2(Y)) \), \( A \in D_1 \) and \( B \in D_2 \).

A characterization similar to the Grothendieck’s one also holds in the measurable setting: the following result was established by Peller [31] (see also Spronk [38]).

**Theorem 2.1.** Let \( \varphi \in L^\infty(X \times Y) \). The following are equivalent:

(i) \( \varphi \) is a Schur multiplier and \( \| \varphi \|_m < C \);

(ii) there exist families \( \{ a_k \}_{k \in \mathbb{N}} \subseteq L^\infty(X) \) and \( \{ b_k \}_{k \in \mathbb{N}} \subseteq L^\infty(Y) \) such that
\[
\operatorname{esssup}_{x \in X} \sum_{k=1}^{\infty} |a_k(x)|^2 < C, \quad \operatorname{esssup}_{y \in Y} \sum_{k=1}^{\infty} |b_k(y)|^2 < C
\]
and
\[
\varphi(x, y) = \sum_{k=1}^{\infty} a_k(x)b_k(y), \quad \text{for almost all } (x, y) \in X \times Y.
\]

We outline the proof of the theorem using results of Smith [37] and Haagerup [21]; this proof relies on the notion of complete boundedness whose mention is deliberately omitted for the time being but will be discussed in detail later.

**Sketch of proof.** Assume \( (X, \mu) = (Y, \nu) \) and \( \varphi \) is a Schur \( \mu, \mu \)-multiplier with \( \| \varphi \|_m < C \). Then \( S_\varphi \) can be extended to a bounded \( D, \mathcal{D} \)-bimodule map on \( \mathcal{K}(L^2(X)) \), where \( \mathcal{D} \) is the multiplication masa of \( L^\infty(X) \). By [37, Theorem 2.1, Theorem 3.1], there exist sequences \( \{ a_k \}_{k=1}^{\infty} \) and \( \{ b_k \}_{k=1}^{\infty} \) in \( L^\infty(X) \) such that \( \| \sum_{k=1}^{\infty} M_{a_k} M_{b_k} \| \| \sum_{k=1}^{\infty} M_{a_k}^* M_{a_k} \| = \| \varphi \|_m^2 \) and, for all \( T \in \mathcal{K}(L^2(X)) \),
\[
S_\varphi(T) = \sum_{k=1}^{\infty} M_{b_k} TM_{a_k},
\]
where the sum on the right hand side converges in the strong operator topology. Let \( \psi \in L^\infty(X \times X) \) be the function given by \( \psi(x, y) = \sum_{k=1}^{\infty} a_k(x)b_k(y) \). For all \( f \in L^2(X \times X) \) we have \( S_\varphi(T_f) = T_\varphi f \) and \( \sum_{k=1}^{\infty} M_{a_k} T_f M_{a_k} = T_\psi f \). We obtain that \( \varphi(x, y)f(x, y) = \psi(x, y)f(x, y) \) for every \( f \in L^2(X \times X) \) and this implies that \( \varphi(x, y) = \psi(x, y) \) for almost all \( (x, y) \in X \times X \).

To obtain the converse statement one should first note that for \( \varphi(x, y) = \sum_{k=1}^{\infty} a_k(x)b_k(y) \) we have that the operator \( S_\varphi(T) \) is given by (2), for all \( T \in \mathcal{C}_2(L^2(X)) \). To complete the proof, one can apply estimation arguments similar to the one in (1). \( \diamond \)
Certain notions pertinent to Measure Theory that were initially introduced by Arveson [1] and later developed in [18] play an important role in the study of measurable Schur multipliers. A subset $E \subseteq X \times Y$ is called **marginally null** if $E \subseteq (M \times Y) \cup (X \times N)$ for some null sets $M \subseteq X$ and $N \subseteq Y$. Two measurable sets $E, F \subseteq X \times Y$ are called **marginally equivalent** if their symmetric difference is marginally null. A measurable subset $\kappa \subseteq X \times Y$ is called **\(\omega\)-open** if $\kappa$ is marginally equivalent to a subset of the form $\bigcup_{i=1}^{\infty} \alpha_i \times \beta_i$, where $\alpha_i \subseteq X$ and $\beta_i \subseteq Y$ are measurable; $\kappa$ is called **\(\omega\)-closed** if its complement is $\omega$-open. The collection of all $\omega$-open subsets of $X \times Y$ is an $\omega$-**topology**; that is, a family of sets closed under finite intersections and countable unions, containing the empty set and the set $X \times Y$. The described $\omega$-topology plays an important role in the theory of masa-bimodules (see [18]). The morphisms of $\omega$-topological spaces are $\omega$-continuous mappings. A function $f : X \times Y \to \mathbb{C}$ is $\omega$-**continuous** if $f^{-1}(U)$ is an $\omega$-open set for every open subset $U \subseteq \mathbb{C}$. The following was shown in [29]:

**Proposition 2.2.** Every $\mu, \nu$-multiplier coincides almost everywhere with an $\omega$-continuous function.

From this result, we immediately obtain that if $\chi_\kappa$ is an idempotent Schur multiplier, where $\kappa \subseteq X \times Y$ then $\kappa$ differs by a null set from a subset that is both $\omega$-closed and $\omega$-open. This fact was pointed out in [27].

The predual of $\mathcal{B}(L^2(X), L^2(Y))$ can be naturally identified with the projective tensor product $L^2(X) \hat{\otimes} L^2(Y)$. Suppose that $h \in L^\infty(X) \hat{\otimes} L^2(Y)$ and let $h = \sum_{k=1}^{\infty} f_k \otimes g_k$ be an associated series for $h$, where $\sum_{k=1}^{\infty} \|f_k\|_2^2 < \infty$ and $\sum_{k=1}^{\infty} \|g_k\|_2^2 < \infty$. These conditions easily imply that the formula

$$h(x, y) = \sum_{k=1}^{\infty} f_k(x)g_k(y), \quad (x, y) \in X \times Y,$$

defines a function (which we denote again by $h$). If the $f_k$’s or the $g_k$’s are replaced by some equivalent functions (with respect to the measures $\mu$ and $\nu$) then the function $h$ will change only on a marginally null set.

Let $\Gamma(X, Y)$ be the set of all functions $h$ defined as above. Another useful result of Peller [31] identifies $S(X, Y)$ as the multiplier algebra of $\Gamma(X, Y)$:

**Proposition 2.3.** A function $\varphi \in L^\infty(X \times Y)$ is a Schur multiplier if and only if $\varphi h \in \Gamma(X, Y)$ for every $h \in \Gamma(X, Y)$.

**Proof.** For $k \in L^2(X \times Y)$ and $h \in \Gamma(X, Y)$, one has $\langle T_k, T_h \rangle = \int khd(\mu \times \nu)$. It follows that $h \in \Gamma(X, Y)$ if and only if

$$\exists C > 0 \quad \left| \int khd(\mu \times \nu) \right| \leq C\|T_k\|_{op} \quad \text{for all } k \in L^2(X \times Y).$$

Now we have that if $\varphi$ is a Schur multiplier then

$$\left| \int \varphi khd(\mu \times \nu) \right| = |\langle S_\varphi(T_k), T_h \rangle| \leq \|\varphi\|_m\|T_k\|_1\|T_k\|_{op} \Leftrightarrow \varphi h \in \Gamma(X, Y).$$
Conversely, if $\varphi h \in \Gamma(X, Y)$ for all $h \in \Gamma(X, Y)$, then by the Closed Graph Theorem, the mapping $T_h \mapsto T_{\varphi h}$ on $C_b(L^2(X), L^2(Y))$ is bounded and

$$|\langle S_{\varphi}(T_k), T_h \rangle| = |\int \varphi kh d(\mu \times \nu)| = |\langle T_k, T_{\varphi h} \rangle| \leq C\|T_k\|_{\text{op}}\|T_h\|_1.$$ 

Thus, $\|S_{\varphi}(T_k)\|_{\text{op}} \leq C\|T_k\|_{\text{op}}$. ⊤

Measurable Schur multipliers are closely related to the theory of double operator integrals developed by Birman and Solomyak in a series of papers [3], [4], [5] (see also the survey paper [6]). We describe here briefly this connection. Let $E(\cdot)$ and $F(\cdot)$ be spectral measures defined on measure spaces $X$ and $Y$, and taking values in the projection lattices of Hilbert spaces $H$ and $K$, respectively. We fix a scalar valued measure $\mu \ (\text{resp. } \nu)$ on $X \ (\text{resp. } Y)$, equivalent to $E \ (\text{resp. } F)$. A double operator integral is a formal expression of the form

$$\mathcal{I}_{\varphi}^{E,F}(T) = \int \varphi(x, y) dE(x) TdF(y),$$

where $\varphi$ is an essentially bounded function defined on $X \times Y$, and $T \in B(K, H)$. A precise meaning can be given to (3) as follows. Let $G$ be the (unique) spectral measure defined on the product $X \times Y$ of the measure spaces $X$ and $Y$ and taking values in the projection lattice of the Hilbert space $C_2(K, H)$, given on measurable rectangles by $G(\alpha \times \beta)(T) = E(\alpha)TF(\beta)$. For $\varphi \in L^\infty(X \times Y, \mu \times \nu)$ and $T \in C_2(K, H)$, let

$$\mathcal{I}_{\varphi}^{E,F}(T) = \left( \int_{X\times Y} \varphi(x, y) dG(x, y) \right)(T).$$

Spectral Theory gives a precise meaning to the right hand side of the above expression, a well-defined element of $C_2(K, H)$. Note that $\mathcal{I}_{\varphi}^{E,F}(T)$ depends only on the equivalence class (with respect to product measure) of the function $\varphi$. For some functions $\varphi$, there may exist a constant $C > 0$ such that

$$\|\mathcal{I}_{\varphi}^{E,F}(T)\|_{\text{op}} \leq C\|T\|_{\text{op}};$$

in this case the mapping $\mathcal{I}_{\varphi}^{E,F}$ extends uniquely to a bounded mapping on $\mathcal{B}(K, H)$, and, after taking second duals, to a bounded mapping on $\mathcal{B}(K, H)$.

Suppose for a moment that the spectral measures $E$ and $F$ are multiplicity free, that is, the (abelian) von Neumann algebras generated by their ranges are maximal. It is easy to note that in this case a function $\varphi$ satisfies the inequality (4) for some constant $C > 0$ if and only if $\varphi$ is a Schur multiplier.

If $E$ possesses non-trivial multiplicity then one can decompose the Hilbert space $H$ as a direct integral $H = \int_X H(x) d\mu(x)$ in such a way that the elements of the abelian von Neumann algebra generated by $E(\cdot)$ are precisely the diagonal operators. Similarly, $K = \int_Y K(y) d\nu(y)$. The space $C_2(K, H)$ possesses a decomposition as $C_2(K, H) = \int_{X \times Y} C_2(K(y), H(x)) d\mu \times \nu(x, y)$. Thus, every element $T$ of $C_2(K, H)$ gives rise to an operator valued “kernel” $(T(x, y))_{x, y}$. We have that $\mathcal{I}_{\varphi}^{E,F}(T)$ is the operator with corresponding kernel.
\((\varphi(x,y)T(x,y))_{x,y}\). In this way, double operator integrals may again be realised as measurable Schur multipliers.

One application of double operator integrals is to perturbation theory, in particular, to the study of operators of the form \(h(A) - h(B)\) depending on the properties of \(A - B\), where \(A, B\) are selfadjoint operators and \(h\) is a function defined on an interval containing the spectra of \(A\) and \(B\).

Assume \(h(x)\) is a uniformly Lipschitz function on \(\mathbb{R}\), and let \(\hat{h}(x,y) = h(x) - h(y)\). This function is well-defined and bounded outside the diagonal \(\{(x, x) : x \in \mathbb{R}\}\). Since the diagonal has measure zero, \(\hat{h}(x,y)\) is well defined up to a null set. Thus, extending it in an arbitrary fashion to a bounded function defined on the whole of \(\mathbb{R} \times \mathbb{R}\) always yields the same element of \(L^\infty(\mathbb{R} \times \mathbb{R})\) which we again denote by \(\hat{h}\).

**Theorem 2.4.** [6] Let \(E(\cdot), F(\cdot)\) be the spectral measures of \(A\) and \(B\) respectively. Suppose that \(\hat{h}\) satisfies (4). Then
\[
h(A) - h(B) = I_{E,F}^h(A - B)
\]
and hence
\[
\|h(A) - h(B)\| \leq C\|A - B\|.
\]

The property of \(\hat{h}\) being a Schur multiplier is closely related to a kind of “operator smoothness” of \(h\). Let \(\alpha\) be a compact set in \(\mathbb{R}\). A continuous function \(h\) on \(\alpha\) is called Operator Lipschitz on \(\alpha\) if there is \(D > 0\) such that
\[
\|h(A) - h(B)\| \leq D\|A - B\|
\]
for all selfadjoint operators \(A, B\) with spectra in \(\alpha\).

**Proposition 2.5.** Let \(I\) be a compact interval. A function \(\hat{h}\) is a Schur multiplier on \(I \times I\) if and only if \(h\) is Operator Lipschitz on \(I\).

The proof of this result is based on the result by Kissin and Shulman [28] that for all compact sets \(I\) of \(\mathbb{R}\) a function \(h\) is Operator Lipschitz on \(I\) if and only if \(h\) is commutator bounded, that is, there exists \(D > 0\) such that for any selfadjoint \(A\) with spectrum in \(I\) and any bounded operator \(X\), the inequality
\[
\|h(A)X - Xh(A)\| \leq D\|AX -XA\|
\]
holds. Note also that if \(A\) is the multiplication operator \((Ag)(x) = xg(x)\) on \(L^2(I, \mu)\) and \(X = T_k\), where \(k(x,y) = (x - y)k_1(x,y)\) for some \(k_1 \in L^2(I \times I, \mu \times \mu)\), then (5) is equivalent to
\[
\|S_h(T_k)\| \leq D\|T_k\|.
\]

For other applications, in particular to differentiation of functions of self-adjoint operators, we refer the reader to [6], and for more results on applications of Schur multipliers to operator inequalities – to [23].
As the connections with double operator integrals shows, the purpose of introducing measurable Schur multipliers is not limited to studying the notion in the greatest possible generality. We now further illustrate this, describing a connection with Harmonic Analysis. Let $G$ be a locally compact group which we assume for technical simplicity to be $\sigma$-compact. We let $L^p(G)$, $p = 1, 2, \infty$, be the corresponding function spaces with respect to the (left) Haar measure. By $\lambda : G \rightarrow B(L^2(G))$ we denote the left regular representation of $G$; thus, $\lambda_s f(t) = f(s^{-1} t)$, $s, t \in G$, $f \in L^2(G)$. We recall that the Fourier algebra $A(G)$ of $G$ is the space of all “matrix coefficients of $G$ in its left regular representation”, that is,

$$A(G) = \{ s \mapsto (\lambda_s \xi, \eta) : \xi, \eta \in L^2(G) \}.$$ 

If $G$ is commutative, then $A(G)$ is the image of $L^1(\hat{G})$ under Fourier transform, where $\hat{G}$ is the dual group of $G$. The Fourier algebra of general locally compact groups was introduced and studied (along with other objects pertinent to Non-commutative Harmonic Analysis) by Eymard in [19]. It is a commutative regular semi-simple Banach algebra of continuous functions vanishing at infinity and has $G$ as its spectrum. Moreover, its Banach space dual is isometric to the von Neumann algebra $VN(G)$ of $G$, that is, the weakly closed subalgebra of $B(L^2(G))$ generated by the operator $\lambda_s$, $s \in G$. The duality between these two spaces is given by the formula $(\langle \lambda_s f, \xi \rangle = f(s^{-1} x))$ (recall that $f \in A(G)$ is a function on $G$).

A function $\varphi \in L^\infty(G)$ is called a multiplier of $A(G)$ if $\varphi f \in A(G)$ for every $f \in A(G)$. The identification of the multipliers of $A(G)$ (which, as is easy to see, form a function algebra on $G$) has received a considerable attention in the literature. A classical result in this direction ([35]) states that if $G$ is abelian then $\varphi$ is a multiplier of $A(G)$ if and only if it is the Fourier transform of a regular Borel measure on $\hat{G}$.

Up to date, a satisfactory characterisation of the multiplier algebra of $A(G)$ is not known. There is, however, a neat and useful characterisation of the subalgebra $M_{cb}(A(G))$ of completely bounded multipliers of $A(G)$ introduced in [10]. In order to define these multipliers, we need the notions of an operator space and a completely bounded map.

An operator space is a complex vector space $\mathcal{X}$ for which a norm $\| \cdot \|_n$ is given on the space $M_n(\mathcal{X})$ of all $n$ by $n$ matrices with entries in $\mathcal{X}$ satisfying the following conditions, called Ruan’s axioms:

(R1) $\| x \otimes y \|_{n+m} = \max \{ \| x \|_n, \| y \|_m \}$, for all $m, n \in \mathbb{N}$ and all $x \in M_n(\mathcal{X})$ and $y \in M_m(\mathcal{X})$;

(R2) $\| \alpha \cdot x \cdot \beta \|_m \leq \| \alpha \| \| \beta \| \| x \|_n$, for all $x \in M_n(\mathcal{X})$, $\alpha \in M_{m,n}(\mathbb{C})$, $\beta \in M_{n,m}(\mathbb{C})$ and all $m, n \in \mathbb{N}$.

In property (R2), we have denoted by $\cdot$ the natural left action of $M_{m,n}$ on $M_n(\mathcal{X})$ as well as the natural right action of $M_{n,m}$ on $M_n(\mathcal{X})$. By $\| \alpha \|$ we mean the norm of the matrix $\alpha \in M_{m,n}$ when considered as an operator from $\mathbb{C}^n$ into $\mathbb{C}^m$ (where $\mathbb{C}^n$ and $\mathbb{C}^m$ are equipped with the $\ell^2$-norm).
If $\mathcal{X}$ and $\mathcal{Y}$ are operator spaces and $\phi : \mathcal{X} \to \mathcal{Y}$ is a linear map, then one may consider the maps $\phi_n : M_n(\mathcal{X}) \to M_n(\mathcal{Y})$ defined by applying the mapping $\phi$ entry-wise. The map $\phi$ is called completely bounded if each $\phi_n$, $n \in \mathbb{N}$, is bounded, and $\sup_{n \in \mathbb{N}} \|\phi_n\| < \infty$. It is called a complete isometry if $\phi_n$ is an isometry for every $n \in \mathbb{N}$. Since complete isometries preserve all the given structure of an operator space, they constitute the right notion of an isomorphism in the category of operator spaces.

If $\mathcal{X}$ is an operator space and $\mathcal{X}^*$ is its dual Banach space, then the space $M_n(\mathcal{X}^*)$ can be naturally identified with the space $\text{CB}(\mathcal{X}, M_n(\mathbb{C}))$ of all completely bounded linear maps from $\mathcal{X}$ into $M_n(\mathbb{C})$. If we equip $M_n(\mathcal{X}^*)$ with the norm coming from this identification, then the obtained family of norms turns $\mathcal{X}^*$ into an operator space.

If $\mathcal{X} \subseteq B(H)$ for some Hilbert space $H$, then $M_n(\mathcal{X})$ is naturally embedded into $B(H^n)$ and hence inherits its operator norm. The family of norms obtained in this way satisfy Ruan’s axioms. Ruan’s representation theorem asserts that every operator space is completely isometric to a subspace of $B(H)$, for some Hilbert space $H$.

After this very brief introduction of the basic notions of Operator Space Theory, we can return to multipliers. From the last paragraph it follows that every von Neumann algebra, in particular $\text{VN}(G)$, is an operator space. Hence its dual, and therefore its predual $A(G)$ (which is a subspace of its dual) possesses a canonical operator space structure. A multiplier $\varphi$ of $A(G)$ is called completely bounded if the mapping $f \to \varphi f$ is completely bounded. Namely, the following was established by Bozejko and Fendler in [9] (see also [33]):

**Theorem 2.6.** If $\varphi \in L^\infty(G)$, let $\tilde{\varphi} \in L^\infty(G \times G)$ be the function given by $\tilde{\varphi}(s,t) = \varphi(s^{-1}t)$. A function $\varphi \in L^\infty(G)$ belongs to $M_{cb}A(G)$ if and only if the function $\tilde{\varphi}$ is a Schur multiplier with respect to the left Haar measure.

3. Going non-commutative

Let $(X, \mu)$ and $(Y, \nu)$ be standard ($\sigma$-finite) measure spaces. It is immediate from the definitions that if $\varphi, \psi \in S(X,Y)$ then $S_{\varphi}S_{\psi} = S_{\varphi \psi}$. Thus, $S_{\varphi}S_{\psi} = S_{\psi}S_{\varphi}$ for every $\varphi, \psi \in S(X,Y)$; in other words, the collection of all mappings $\{S_{\varphi} : \varphi \in S(X,Y)\}$ is commutative. In view of the contemporary trend in Functional Analysis to seek non-commutative versions of “classical” notions and results [7], [16], [30], [34], it is natural to ask whether there is a natural non-commutative, or “quantised” version of Schur multipliers. This question was pursued by Kissin and Shulman in [29], and is the topic of this section.

For a Hilbert space $H$, we write $H^d$ for the (Banach space) dual of $H$. There exists a conjugate-linear surjective isometry $\partial : H \to H^d$ given by $\partial(x)(y) = (y, x)$, $x, y \in H$.

Let $H$ and $K$ be Hilbert spaces and $\theta : H \otimes K \to C_2(H^d, K)$ be the natural surjective isometry from the Hilbert space tensor product $H \otimes K$ onto the
space $C_2(H^d, K)$ of all Hilbert-Schmidt operators from $H^d$ into $K$ given by 
\[ \theta(x \otimes y)(z^d) = (x, z)y. \] 
This identification allows us to equip $H \otimes K$ with an “operator” norm: if $\xi \in H \otimes K$, let $\|\xi\|_{\text{op}} = \|\theta(\xi)\|_{\text{op}}$. We call an element $\varphi \in B(H \otimes K)$ a concrete operator multiplier if there exists a constant $C > 0$ such that $\|\varphi\xi\|_{\text{op}} \leq C\|\xi\|_{\text{op}}$, for every $\xi \in H \otimes K$. We call the smallest possible constant $C$ with this property the concrete multiplier norm of $\varphi$. It follows from this definition that the set $\mathcal{M}(H, K)$ of all concrete operator multipliers on $H \otimes K$ is a subalgebra of $B(H \otimes K)$. It is also immediate that if $H = L^2(X, \mu)$ and $K = L^2(Y, \nu)$ for some standard measure spaces $(X, \mu)$ and $(Y, \nu)$ and $\varphi$ is the multiplication operator on $L^2(X \times Y) = L^2(X) \otimes L^2(Y)$ corresponding to a function $\hat{\varphi} \in L^\infty(X \times Y)$ then $\varphi$ is a concrete operator multiplier if and only if $\hat{\varphi}$ is a Schur $\mu, \nu$-multiplier. Thus, the algebra $\mathcal{M}(H, K)$ contains $S(X, Y)$ as a commutative subalgebra. Note that there are “many” commutative subalgebras of $\mathcal{M}(H, K)$ of this form, one for each realisation of $H$ and $K$ as $L^2$-spaces over some standard measure spaces.

In the commutative theory, a special interest has been paid to the case where the measure spaces $(X, \mu)$ and $(Y, \nu)$ are regular Borel spaces of complete metrisable topologies, and the multipliers $\varphi$ are continuous functions on $X \times Y$. The non-commutative expression of continuous functions is given in terms of C*-algebras. Therefore, it is natural to extend the setting of concrete operator multipliers given above as follows. Suppose that $A$ and $B$ are unital C*-algebras and $\pi : A \to B(H_\pi)$ and $\rho : B \to B(H_\rho)$ are *-representations. It is well-known that there exists a unique *-representation $\pi \otimes \rho$ of the minimal tensor product $A \otimes B$ of $A$ and $B$ on $H_\pi \otimes H_\rho$. An element $\varphi \in A \otimes B$ is called a $\pi, \rho$-multiplier \[29\] if $(\pi \otimes \rho)(\varphi)$ is a concrete operator multiplier. We let $\|\varphi\|_{\pi, \rho}$ be the concrete operator multiplier norm of $(\pi \otimes \rho)(\varphi)$. 

Let $\mathcal{M}^{\pi, \rho}(A, B)$ be the set of all $\pi, \rho$-multipliers. It is immediate that 
$\mathcal{M}^{\pi, \rho}(A, B)$ is a subalgebra of $A \otimes B$ containing the algebraic tensor product $A \otimes B$. To see the last statement, note that if $a \in A$ and $b \in B$ then 
\[ \theta(\pi \otimes \rho)(a \otimes b)(\xi) = \rho(b)\theta(\hat{\varphi}) \pi(a)\xi, \] 
for every $\xi \in H_\pi \otimes H_\rho$; we hence have that $\|a \otimes b\|_{\pi, \rho} \leq \|a\| \|b\|$. 

We let $\mathcal{M}(A, B) = \cap_{\pi, \rho} \mathcal{M}^{\pi, \rho}(A, B)$ where the intersection is taken over all representations $\pi$ of $A$ and $\rho$ of $B$. The elements of $\mathcal{M}(A, B)$ are called universal multipliers. By the previous paragraph, every element of the algebraic tensor product $A \otimes B$ is a universal multiplier. It is not difficult to see that if $\varphi \in \mathcal{M}(A, B)$ then $\|\varphi\|_m \overset{\text{def}}{=} \sup_{\pi, \rho} \|\varphi\|_{\pi, \rho}$ is finite; we call $\|\varphi\|_m$ the (universal) multiplier norm of $\varphi$.

Two immediate questions arise:

(a) How does the algebra $\mathcal{M}^{\pi, \rho}(A, B)$ depend on $\pi$ and $\rho$?

(b) Is there a characterisation of its elements extending the Grothendieck-Peller’s characterisation of Schur multipliers?
It was observed by Kissin and Shulman [29] that (a) is related to the
notion of approximate equivalence of representations due to Voiculescu [41]
and its extension, the approximate sub-ordinance introduced by Hadwin
[22]. We recall these notion here. Let $\pi$ and $\pi'$ be $*$-representations of a
$C^*$-algebra $\mathcal{A}$ on Hilbert spaces $H$ and $H'$, respectively. We say that $\pi'$ is
approximately subordinate to $\pi$ and write $\pi' \lessapprox \pi$ if there is a net \{${U_\lambda}$\} of
isometries from $H'$ to $H$ such that

$$\|\pi(a)U_\lambda - U_\lambda \pi'(a)\| \to 0 \quad \text{for all } a \in \mathcal{A}.$$  

(6)

The representations $\pi'$ and $\pi$ are said to be approximately equivalent if the
operators $U_\lambda$ can be chosen to be unitary; in this case we write $\pi' \sim \pi$.

The following result was established in [29]:

**Theorem 3.1** (Comparison Theorem). Let $\mathcal{A}$ and $\mathcal{B}$ be $C^*$-algebras and $\pi$,
$\pi'$ (resp. $\rho$, $\rho'$) be representations of $\mathcal{A}$ (resp. $\mathcal{B}$). Suppose that $\pi' \lessapprox \pi$
and $\rho' \lessapprox \rho$. Then $\mathfrak{M}^{\pi,\rho}(\mathcal{A}, \mathcal{B}) \subseteq \mathfrak{M}^{\pi',\rho'}(\mathcal{A}, \mathcal{B})$.
Moreover, if $\varphi \in \mathfrak{M}^{\pi,\rho}(\mathcal{A}, \mathcal{B})$
then $\|\varphi\|_{\pi',\rho'} \leq \|\varphi\|_{\pi,\rho}$.

In particular, if $\pi' \sim \pi$ and $\rho' \sim \rho$ then $\mathfrak{M}^{\pi,\rho}(\mathcal{A}, \mathcal{B}) = \mathfrak{M}^{\pi',\rho'}(\mathcal{A}, \mathcal{B})$ and
$\|\varphi\|_{\pi',\rho'} = \|\varphi\|_{\pi,\rho}$ for every $\varphi \in \mathfrak{M}^{\pi,\rho}(\mathcal{A}, \mathcal{B})$.

We note that, by [22], $\pi' \lessapprox \pi$ if and only if

$$\text{rank } \pi'(a) \leq \text{rank } \pi(a), \quad \text{for every } a \in \mathcal{A}.$$  

Theorem 3.1 has some interesting consequences about measurable and
classical Schur multipliers [29]:

**Corollary 3.2.** Let $X$ and $Y$ be locally compact Hausdorff spaces with countable bases, and let $\mu$ and $\mu'$ (resp. $\nu$ and $\nu'$) be $\sigma$-finite Borel measures on $X$ (resp. $Y$). Suppose that $\text{supp } \mu' \subseteq \text{supp } \mu$ and $\text{supp } \nu' \subseteq \text{supp } \nu$. Then every $\mu, \nu$-multiplier in $\mathcal{C}_0(X \times Y)$ is also a $\mu', \nu'$-multiplier.

In particular, if $\text{supp } \mu = X$ and $\text{supp } \nu = Y$ then an element $\varphi \in \mathcal{C}_0(X \times Y)$ is a $\mu, \nu$-multiplier if and only if $\varphi$ is a classical Schur multiplier on $X \times Y$.

There is a version of the last result for functions $\varphi$ that are not required to be continuous [29]:

**Theorem 3.3.** Let $(X, \mu)$ and $(Y, \nu)$ be standard $\sigma$-finite measure spaces and $\varphi \in L^\infty(X \times Y)$ be an $\omega$-continuous function. The following are equivalent:

(i) $\varphi$ is a $\mu, \nu$-multiplier;
(ii) there exist null sets $X_0 \subseteq X$ and $Y_0 \subseteq Y$ such that the restriction $\tilde{\varphi}$ of $\varphi$ to $(X \setminus X_0) \times (Y \setminus Y_0)$ is a classical Schur multiplier.

Moreover, if (i) holds then the sets $X_0$ and $Y_0$ can be chosen in such a way that the $\mu, \nu$-multiplier norm of $\varphi$ equals the classical Schur multiplier norm of $\tilde{\varphi}$. 

SCHUR AND OPERATOR MULTIPLIERS 13
We now address Question (b) above concerning the characterisation of operator multipliers. At the moment, no such characterisation is known for the classes $\mathcal{M}^\ast\omega(\mathcal{A},\mathcal{B})$. The reason lies in the lack of complete boundedness, which we now explain. Suppose that $\mathcal{A} \subseteq \mathcal{B}(H)$ and $\mathcal{B} \subseteq \mathcal{B}(K)$ are concrete $C^*$-algebras, and take an element $\varphi \in \mathcal{M}^\ast\omega(\mathcal{A},\mathcal{B})$, where $\text{id}$ denotes the identity representations of $\mathcal{A}$ and $\mathcal{B}$ on $H$ and $K$, respectively. Since $\varphi$ is a concrete operator multiplier on $H \otimes K$, we have that the mapping $S_\varphi : \mathcal{C}_2(H^d, K) \rightarrow \mathcal{C}_2(H^d, K)$ given by $S_\varphi(\theta(x)) = \theta(\varphi x)$, has a canonical extension to a bounded mapping (denoted in the same way) $S_\varphi : \mathcal{K}(H^d, K) \rightarrow \mathcal{K}(H^d, K)$. By passing to second duals, we arrive at a bounded mapping $S_\varphi^{**} : \mathcal{B}(H^d, K) \rightarrow \mathcal{B}(H^d, K)$. In general, however, the mappings $S_\varphi$ and $S_\varphi^{**}$ need not be completely bounded. If $\varphi$ is assumed to lie in the smaller class $\mathcal{M}(\mathcal{A},\mathcal{B})$ of universal multipliers, then the mappings $S_\varphi$ and $S_\varphi^{**}$ turn out to be completely bounded. This can be seen by considering the $n$-fold ampliations $\text{id}^{(n)}$ of the identity representations of $\mathcal{A}$ and $\mathcal{B}$. In fact, the following statement [25] shows that in order to decide whether an element $\varphi \in \mathcal{A} \otimes \mathcal{B}$ is a universal multiplier, it suffices to check that it is a $\text{id}^{(n)}$, $\text{id}^{(n)}$-multiplier for all $n \in \mathbb{N}$. The proof of this result uses the Comparison Theorem 3.1.

**Proposition 3.4.** Let $\mathcal{A} \subseteq \mathcal{B}(H)$ and $\mathcal{B} \subseteq \mathcal{B}(K)$. An element $\varphi \in \mathcal{A} \otimes \mathcal{B}$ is a universal multiplier if and only if the (weak* continuous) mapping $S_\varphi^{**}$ is completely bounded.

The structure of normal (that is, weak* continuous) completely bounded maps on $\mathcal{B}(K, H)$ is well understood. We recall a well-known result of Haagerup [21]: a mapping $\Phi : \mathcal{B}(K, H) \rightarrow \mathcal{B}(K, H)$ is normal and completely bounded if and only if there exist families $\{a_k\}_{k=1}^\infty \subseteq \mathcal{B}(H)$ and $\{b_k\}_{k=1}^\infty \subseteq \mathcal{B}(K)$ such that the series $\sum_{k=1}^\infty a_k a_k^\ast$ and $\sum_{k=1}^\infty b_k b_k^\ast$ are weak* convergent and

$$\Phi(x) = \sum_{k=1}^\infty a_k x b_k, \quad \text{for all } x \in \mathcal{B}(K, H).$$

Thus, one may associate with every normal completely bounded map $\Phi$ on $\mathcal{B}(K, H)$ a formal series $\sum_{k=1}^\infty a_k \otimes b_k$ where the families $\{a_k\}_{k=1}^\infty \subseteq \mathcal{B}(H)$ and $\{b_k\}_{k=1}^\infty \subseteq \mathcal{B}(K)$ are assumed to satisfy the above convergence conditions. Two such formal series are identified if the corresponding mappings are equal. The collection of all such series is known as the weak* (or the extended) Haagerup tensor product of $\mathcal{B}(H)$ and $\mathcal{B}(K)$ and denoted by $\mathcal{B}(H) \otimes_{\text{eh}} \mathcal{B}(K)$. In fact, $\mathcal{B}(H) \otimes_{\text{eh}} \mathcal{B}(K)$ can be viewed as a certain weak completion of the algebraic tensor product $\mathcal{B}(H) \otimes \mathcal{B}(K)$ (see [8] where this tensor product was introduced).

The weak* Haagerup tensor product can be defined for any pair of dual operator spaces $\mathcal{X}^*$ and $\mathcal{Y}^*$ and is the dual operator space of the **Haagerup tensor product** $\mathcal{X} \otimes_{\text{h}} \mathcal{Y}$ of $\mathcal{X}$ and $\mathcal{Y}$. The latter is the tensor product
that linearises completely bounded bilinear mappings. These are defined as follows: Suppose that $\phi : \mathcal{X} \times \mathcal{Y} \to \mathcal{Z}$ is a bilinear mapping, where $\mathcal{Z}$ is another operator space. One may define the mappings $\phi^{(n)} : M_n(\mathcal{X}) \times M_n(\mathcal{Y}) \to M_n(\mathcal{Z})$, $n \in \mathbb{N}$, by $\phi^{(n)}((x_{i,j}), (y_{k,l})) = (\sum_{k=1}^{n} \phi(x_{i,k}, y_{k,j}))_{i,j}$. The mapping $\phi$ is called completely bounded if $\|\phi\|_{cb} \overset{def}{=} \sup_{n \in \mathbb{N}} \|\phi^{(n)}\| < \infty$.

The operator space $\mathcal{X} \otimes_{\alpha} \mathcal{Y}$ has the property that for every completely bounded bilinear mapping $\phi : \mathcal{X} \times \mathcal{Y} \to \mathcal{Z}$ the linearised mapping $\tilde{\phi}$ is completely bounded as a map from $\mathcal{X} \otimes_{\alpha} \mathcal{Y}$ into $\mathcal{Z}$ with the same cb norm.

We note that we will introduce later a generalisation of the above notion of complete boundedness to multilinear maps.

The correspondence between elements of $\mathcal{B}(H) \otimes_{eh} \mathcal{B}(K)$ and normal completely bounded mappings on $\mathcal{B}(K, H)$ is bijective: if $u \in \mathcal{B}(H) \otimes_{eh} \mathcal{B}(K)$, we write $\Phi_u$ for the corresponding mapping. The space $\mathcal{B}(H) \otimes_{eh} \mathcal{B}(K)$ is an operator space in its own right (indeed, we have the completely isometric identification $\mathcal{B}(H) \otimes_{eh} \mathcal{B}(K) = (\mathcal{C}_1(H) \otimes_{h} \mathcal{C}_1(K))^*$), and the norm $\|u\|_{eh}$ of an element $u$ is equal to the completely bounded norm of $\Phi_u$.

The extended Haagerup tensor product can be defined for every pair of operator spaces [17]. To do this, we follow the approach given in [38]. Let $\mathcal{E} \subseteq \mathcal{B}(H)$ and $\mathcal{F} \subseteq \mathcal{B}(K)$ be norm closed subspaces. Then the extended Haagerup tensor product $\mathcal{E} \otimes_{eh} \mathcal{F}$ of $\mathcal{E}$ and $\mathcal{F}$ is the subspace

$$\{u \in \mathcal{B}(H) \otimes_{eh} \mathcal{B}(K) : \text{id} \otimes \omega(u) \in \mathcal{E}, \tau \otimes \text{id}(u) \in \mathcal{F}, \forall \omega \in \mathcal{B}(K)_*, \tau \in \mathcal{B}(H)_*\}.$$ 

Here, id $\otimes \omega$ (resp. $\tau \otimes \text{id}$) is the left (resp. right) slice map from $\mathcal{B}(H) \otimes_{eh} \mathcal{B}(K)$ into $\mathcal{B}(H)$ (resp. $\mathcal{B}(K)$) along the functional $\omega$ (resp. $\tau$). The fact that these maps are well-defined needs a justification that we omit.

The extended Haagerup tensor product of operator spaces is functorial: if $f : \mathcal{E} \to \mathcal{E}'$ and $g : \mathcal{F} \to \mathcal{F}'$ are completely bounded maps then there exists a unique completely bounded map $f \otimes g : \mathcal{E} \otimes_{eh} \mathcal{F} \to \mathcal{E}' \otimes_{eh} \mathcal{F}'$ given on elementary tensors by $(f \otimes g)(a \otimes b) = f(a) \otimes g(b)$. Moreover, if $f$ and $g$ are complete isometries then so is $f \otimes g$ [17].

We now return to universal multipliers. Recall that we have fixed two C*-algebras $\mathcal{A} \subseteq \mathcal{B}(H)$ and $\mathcal{B} \subseteq \mathcal{B}(K)$. Suppose that $\varphi \in \mathcal{A} \otimes \mathcal{B}$ is a universal multiplier. By Proposition 3.4, the map $S^*_{\varphi} : \mathcal{B}(H^d, K) \to \mathcal{B}(H^d, K)$ is completely bounded. Thus, by Haagerup's result described above, there exists an element $u \in \mathcal{B}(K) \otimes_{eh} \mathcal{B}(H^d)$ such that $S^*_{\varphi} = \Phi_u$. It was shown in [26] that, in fact, $u$ lies in the extended Haagerup tensor product $\mathcal{B} \otimes_{eh} \mathcal{A}^d$, and that it does not depend on the concrete representations of the C*-algebras $\mathcal{A}$ and $\mathcal{B}$ that we started with. More precisely, the following “symbolic calculus” result holds. (We denote by $\mathcal{A}^o$ the opposite C*-algebra of $\mathcal{A}$ which coincides with $\mathcal{A}$ as an involutive normed linear space but is equipped with the product $a \circ b = ba$. For a representation $\pi : \mathcal{A} \to \mathcal{B}(H)$ we let $\pi^d : \mathcal{A}^o \to \mathcal{B}(H^d)$ be the representation given by $\pi^d(a^o) = \pi(a)^d$.)

**Theorem 3.5 (Symbolic Calculus for universal multipliers).** Let $\mathcal{A}$ and $\mathcal{B}$ be C*-algebras. There exists an injective homomorphism $\varphi \to u_\varphi$ from $\mathfrak{M}(\mathcal{A}, \mathcal{B})$
into $\mathcal{B} \otimes_{\text{ch}} \mathcal{A}^\circ$ with the following universal property: if $\pi : \mathcal{A} \to \mathcal{B}(H)$ and $\rho : \mathcal{B} \to \mathcal{B}(K)$ are *-representations then

$$S_{\pi \otimes \rho}(\varphi) = \Phi_{\rho \otimes \pi^a(u_\varphi)}.$$ 

Moreover, $\|\varphi\|_m = \|u_\varphi\|_{\text{ch}}$, and $u_{a \otimes b} = b \otimes a^\circ$, for all $a \in \mathcal{A}$, $b \in \mathcal{B}$.

We call the element $u_\varphi$ the symbol of the universal multiplier $\varphi$. The term “symbolic calculus” was first used in the context of Schur multipliers by Katavolos and Paulsen [27] where they explored the correspondence between a measurable Schur multiplier $\varphi$ and the mapping $S_\varphi$.

Suppose now that $\varphi \in \mathcal{M}(\mathcal{A}, \mathcal{B})$. The corresponding symbol $u_\varphi$ has an associated series $\sum_{i=1}^\infty b_i \otimes a_i^\nu$, where $a_i \in \mathcal{A}$ and $b_i \in \mathcal{B}$, $i \in \mathbb{N}$. Let $u_N = \sum_{i=1}^N b_i \otimes a_i^\nu$ and $\varphi_N = \sum_{i=1}^N a_i \otimes b_i \in \mathcal{A} \otimes \mathcal{B}$, $N \in \mathbb{N}$. By Symbolic Calculus, $u_{\varphi_N} = u_N$; moreover, $u_\varphi = \text{w}^*-\lim_{N \to \infty} u_N$. We also have that $\|\varphi_N\|_m = \|u_N\|_{\text{ch}} \leq \|u_\varphi\|_{\text{ch}}$ for all $N \in \mathbb{N}$. These observations can be used to prove the next result which is the appropriate generalisation of Grothendieck’s and Peller’s theorems. Before its formulation, we note that it is easy to see that, for an element $v \in \mathcal{B} \otimes \mathcal{A}^\circ$, we have

$$\|v\|_{\text{ch}} = \inf \left\{ \left( \sum_{i=1}^k d_i d_i^* \right)^{1/2} \left( \sum_{i=1}^k c_i c_i^* \right)^{1/2} : v = \sum_{i=1}^k d_i \otimes c_i^\nu \right\}.$$ 

For en element $\psi = \sum_{i=1}^k c_i \otimes d_i \in \mathcal{A} \otimes \mathcal{B}$, we let $\|\psi\|_{\text{ph}} = \|\sum_{i=1}^k d_i \otimes c_i^\nu\|_{\text{ch}}$.

**Theorem 3.6 (Characterisation Theorem).** Let $\mathcal{A}$ and $\mathcal{B}$ be $C^*$-algebras and $\varphi \in \mathcal{A} \otimes \mathcal{B}$. The following statements are equivalent:

(i) $\varphi \in \mathcal{M}(\mathcal{A}, \mathcal{B})$ and $\|\varphi\|_m < C$;

(ii) There exists a net $\{\varphi_\alpha\} \subseteq \mathcal{A} \otimes \mathcal{B}$ such that $\|\varphi_\alpha\|_{\text{ph}} < C$ for all $\alpha$ and $(\pi \otimes \rho)(\varphi_\alpha) \to_{\alpha} (\pi \otimes \rho)(\varphi)$ weakly, for every pair $\pi, \rho$ of irreducible representations of $\mathcal{A}$ and $\mathcal{B}$.

In the case $\mathcal{A} = C(X)$ and $\mathcal{B} = C(Y)$ are (unital) $C^*$-algebras ($X$ and $Y$ being compact Hausdorff spaces), we obtain the following fact as a consequence of the Characterisation Theorem, which shows that it does extend Theorem 2.1 to the non-commutative case: If $\mu$ and $\nu$ are regular Borel measures on $X$ and $Y$, respectively, then a function $\varphi \in C(X \times Y)$ is a $\mu, \nu$-multiplier if and only if there exist families $\{a_i\}_{i=1}^\infty \subseteq C(X)$ and $\{b_i\}_{i=1}^\infty \subseteq C(Y)$ such that, if $\varphi_k \in C(X \times Y)$ is given by $\varphi_k(x, y) = \sum_{i=1}^k a_i(x) b_i(y)$, $(x, y) \in X \times Y$, then $\sup_{k \in \mathbb{N}} \|\varphi_k\|_m < \infty$ and $\varphi_k \to \varphi$ pointwise $\mu \times \nu$-almost everywhere.

We now turn our attention to a subclass of universal multipliers; in order to define it we recall a notion of compactness of completely bounded maps introduced by Saar in [36]. Let $\mathcal{E}$ and $\mathcal{F}$ be operator spaces and $\Phi : \mathcal{E} \to \mathcal{F}$ be a completely bounded map. One calls $\Phi$ completely compact if for every $\epsilon > 0$ there exists a finite dimensional subspace $\mathcal{F}_0 \subseteq \mathcal{F}$ such that
\[ \text{dist}(\Phi(n)(x), M_n(F_n)) < \epsilon, \text{ for every } x \text{ in the unit ball of } M_n(X), \text{ and for every } n \in \mathbb{N}. \text{ Clearly, every completely compact map is compact.} \]

The following characterisation of completely compact maps on \( K(H) \) was obtained in [36] and later in [26] using a different method.

**Theorem 3.7.** A completely bounded map \( \Phi : K(H) \to K(H) \) is completely compact if and only if there exist sequences \( \{a_i\}, \{b_i\} \subseteq K(H) \) such that the series \( \sum_{i=1}^{\infty} b_i b_i^* \) and \( \sum_{i=1}^{\infty} a_i^* a_i \) are norm convergent and

\[
\Phi(x) = \sum_{i=1}^{\infty} b_i x a_i, \quad \text{for all } x \in K(H).
\]

We call an element \( \varphi \in M(A, B) \) a **compact** (resp. **completely compact**) multiplier if there exist faithful representations \( \pi \) and \( \rho \) of \( A \) and \( B \), respectively, such that the mapping \( S_{\pi \otimes \rho}(\varphi) \) is compact (resp. completely compact). It is clear that every completely compact multiplier is compact.

It was shown in [26] that an element \( \varphi \in M(A, B) \) is (completely) compact if and only if the mapping \( S_{\pi \otimes \rho}(\varphi) \) is (completely) compact, where \( \pi \) (resp. \( \rho \)) is the reduced atomic representation of \( A \) (resp. \( B \)). This is rather natural to expect: let us recall a result of Ylinen concerning the compact elements of a C*-algebra. An element \( a \in A \) is called **compact** if the mapping \( x \to axa \) on \( A \) is compact. Ylinen [42] showed that an element \( a \in A \) is compact if and only if there exists a faithful representation \( \pi \) of \( A \) such that \( \pi(a) \) is a compact operator; moreover, this happens if and only if \( \pi(a) \) is a compact operator.

Let us denote by \( K(A) \) the set of all compact elements of \( A \); it is well-known that \( K(A) \) is a closed two sided ideal of \( A \). By virtue of Ylinen’s result, \( K(A) \) is *-isomorphic to a C*-algebra of compact operators, and is hence *-isomorphic to a \( c_0 \)-direct sum of the form \( \bigoplus_{j \in J} K(H_j) \), for some index set \( J \) and some Hilbert spaces \( H_j, j \in J \).

In the theorem that follows, we view the Haagerup tensor product \( E \otimes_h F \) of two operator spaces \( E \) and \( F \) as sitting completely isometrically in their extended Haagerup tensor product \( E \otimes_{eh} F \).

**Theorem 3.8.** Let \( A \) and \( B \) be C*-algebras and \( \varphi \in M(A, B) \). The following statements are equivalent:

(i) \( \varphi \) is a completely compact multiplier;

(ii) \( u_\varphi \in K(B) \otimes_{eh} K(A^\circ) \);

(iii) there exists a sequence \( \{\varphi_k\}_{k=1}^{\infty} \subseteq K(A) \cap K(B) \) such that \( \|\varphi - \varphi_k\|_m \to k \to \infty 0 \).

Of course, it is natural to ask what happens if \( \varphi \) is only assumed to be a compact multiplier. One may show [26, Proposition 7.1] that if \( \varphi \in M(A, B) \) is a compact multiplier then \( u_\varphi \in K(B) \otimes_{eh} K(A^\circ) \); however, the converse statement fails. We do not have at present a complete characterisation of the compact universal multipliers; however, the following “automatic complete compactness” result holds:
Theorem 3.9. Let \( \mathcal{A} \) and \( \mathcal{B} \) be C*-algebras. Assume that \( \mathcal{K}(\mathcal{A}) \cong \bigoplus_{i \in J_1} M_{n_i} \) and \( \mathcal{K}(\mathcal{B}) \cong \bigoplus_{j \in J_2} M_{m_j} \), where sup_{i \in J_1} n_i and sup_{j \in J_2} m_j are both finite. Then every compact multiplier \( \varphi \in \mathcal{M}(\mathcal{A}, \mathcal{B}) \) is automatically completely compact.

We now see that Theorem 3.8 generalises Hladnik’s description of compact Schur multipliers (Theorem 1.3) since in this case, by Theorem 3.9, every compact multiplier is automatically completely compact.

In the case that sup_{i \in J_1} n_i and sup_{j \in J_2} m_j are both infinite, we were able to exhibit in [26] a compact multiplier \( \varphi \in \mathcal{M}(\mathcal{A}, \mathcal{B}) \) that is not completely compact. The construction is based on an example of Saar [36] of a compact Schur multiplier and an example of Effros [15] of a compact multiplier (Theorem 1.3) since in this case, by Theorem 3.9, every compact multiplier is automatically completely compact.

Theorem 3.10. Let \( \mathcal{A} \) and \( \mathcal{B} \) be C*-algebras. The following statements are equivalent:

(i) Every element of \( \mathcal{M}(\mathcal{A}, \mathcal{B}) \) is a compact multiplier;

(ii) Either \( \mathcal{A} \) is finite dimensional and \( \mathcal{K}(\mathcal{B}) = \mathcal{B} \) or \( \mathcal{B} \) is finite dimensional and \( \mathcal{A} \) is \( \mathcal{K}(\mathcal{A}) \).

The proof is based, in particular, on a result of Varopoulos [40] showing that if \( X, Y \) are infinite compact Hausdorff spaces then there exists a sequence \( (f_i)_{i \in \mathbb{N}} \subseteq C(X) \otimes_h C(Y) \) such that sup_{i \in \mathbb{N}} \|f_i\| < \infty \) converges uniformly to a function \( f \in C(X \times Y) \setminus C(X) \otimes_h C(Y) \). By the Characterisation Theorem 3.6, such an \( f \) must belong to \( \mathcal{M}(C(X), C(Y)) \).

4. Going multidimensional

In the present section, we introduce a multidimensional version of Schur and operator multipliers. If \( R_1, \ldots, R_{n+1} \) are rings, \( M_i \) is a \( R_i \)-left and \( R_{i+1} \)-right module for each \( i = 1, \ldots, n \), and \( M \) is an \( R_1 \)-left and \( R_{n+1} \)-right module, a multilinear map \( \Phi : M_1 \times \cdots \times M_n \to M \) is called \( R_1, \ldots, R_{n+1} \)-modular (or simply modular if \( R_1, \ldots, R_{n+1} \) are clear from the context) if

\[
\Phi(a_1 a_2 a_3, \ldots, a_n a_{n+1}) = a_1 \Phi(m_1, a_2 a_3, \ldots, a_n a_{n+1}),
\]

for all \( m_i \in M_i \) \( (i = 1, \ldots, n) \) and \( a_j \in R_j \) \( (j = 1, \ldots, n+1) \).

A multilinear Schur product was introduced by Effros and Ruan [15] as a multilinear map \( T : M_n(\mathbb{C}) \times \cdots \times M_n(\mathbb{C}) \to M_n(\mathbb{C}) \) which is \( D_n \)-modular, where \( D_n \) is the algebra of all diagonal matrices in \( M_n(\mathbb{C}) \).

It is not difficult to see that any such mapping \( T \) has the form

\[
T(a^r_1, \ldots, a^r_n)_{i,j} = \sum_{(k_1, \ldots, k_r)} A_{i,j}^{k_r \cdots k_1} a_{i,k_r \cdots k_1}^{r-1} a_{k_r-1,k_{r-2}} \cdots a_{k_1,j}.
\]
Suppose \( a^t = (a^t_{k,l})_{k,l} \) and, given the usual matrix units \( e_{i,j} \in M_n(\mathbb{C}) \),
\[
A^{k_r-1\ldots k_1}_{i,j} = T(e_{i,k_r-1}, e_{k_r-1,k_{r-2}}\ldots e_{k_1,j}).
\]

The following theorem gives a characterisation of all bounded multilinear Schur products.

**Theorem 4.1.** Suppose \( T : M_n(\mathbb{C}) \times \cdots \times M_n(\mathbb{C}) \rightarrow M_n(\mathbb{C}) \) is a multilinear Schur product map. Then the following are equivalent:

(i) the linearisation of \( T \) is a contraction for the Haagerup norm;

(ii) there exists a Hilbert space \( H \), \( 2n \) contractions \( a_t(j) \in B(H, \mathbb{C}) \), \( a_r(i) \in B(\mathbb{C}, H) \), \( i,j = 1, \ldots, n \) and \( n^{r-1} \) contractions \( a_t(k) \in B(H) \), \( l = 2, \ldots, r-1, k = 1, \ldots, n \) such that
\[
A^{k_r-1\ldots k_1}_{i,j} = a_r(i)a_{r-1}(k_{r-1})\ldots a_2(k_1)a_1(j).
\]

The theorem was proved in [15] for complete contraction \( T \). A generalisation of Smith’s result [37, Theorem 2.1] to the multidimensional setting, [25, Lemma 3.3], giving that any \( D_n, D_n \)-modular contraction \( T \) is a complete contraction allows us to formulate the statement in this generality. More about completely bounded multilinear maps will be said later.

We now introduce multidimensional measurable Schur multipliers following [25].

Let \( (X_i, \mu_i), \; i = 1, \ldots, n, \) be standard \( \sigma \)-finite measure spaces. For notational convenience, integration with respect to \( \mu_i \) will be denoted by \( dx_i \). Let
\[
\Gamma(X_1, \ldots, X_n) = L^2(X_1 \times X_2) \odot L^2(X_2 \times X_3) \odot \cdots \odot L^2(X_{n-1} \times X_n),
\]
where each product \( X_i \times X_{i+1} \) is equipped with the corresponding product measure.

We identify the elements of \( \Gamma(X_1, \ldots, X_n) \) with functions on
\[
X_1 \times X_2 \times X_2 \times \cdots \times X_{n-1} \times X_{n-1} \times X_n
\]
in the obvious fashion and equip \( \Gamma(X_1, \ldots, X_n) \) with two norms; one is the projective norm \( \| \cdot \|_{2, \Lambda} \), where each of the \( L^2 \)-spaces is equipped with its \( L^2 \)-norm, and the other is the Haagerup tensor norm \( \| \cdot \|_h \), where the \( L^2 \)-spaces are given their opposite operator space structure arising from the identification of \( L^2(X \times Y) \) with the class of Hilbert-Schmidt operators from \( L^2(X) \) into \( L^2(Y) \) given by \( f \mapsto T_f \).

For each \( \varphi \in L^\infty(X_1 \times \cdots \times X_n) \), we consider a linear map \( S_\varphi \) defined on \( \Gamma(X_1, \ldots, X_n) \) and taking values in \( L^2(X_1 \times X_n) \); for an elementary tensor \( f_1 \otimes \cdots \otimes f_{n-1} \) in \( \Gamma(X_1, \ldots, X_n) \), we set \( S_\varphi(f_1 \otimes \cdots \otimes f_{n-1})(x_1, x_n) \) to be equal to
\[
\int_{X_2 \times \cdots \times X_{n-1}} \varphi(x_1, \ldots, x_n)f_1(x_1, x_2)f_2(x_2, x_3)\cdots f_{n-1}(x_{n-1}, x_n)dx_2\ldots dx_{n-1}.
\]
One can show that $S_{\varphi}$ is bounded as a map from $(\Gamma(X_1, \ldots, X_n), \| \cdot \|_2)$ into $(L^2(X_1 \times X_n), \| \cdot \|_2)$. Moreover, any multilinear bounded map $\tilde{S} : L^2(X_1 \times X_2) \times L^2(X_2 \times X_3) \times \cdots \times L^2(X_{n-1} \times X_n) \to L^2(X_1 \times X_n)$ which is $L^\infty(X_1) \cdots L^\infty(X_n)$-modular is given by (T) in analogy with Effros-Ruan’s multilinear Schur product.

If, moreover, $S_{\varphi}$ is bounded as a map from $(\Gamma(X_1, \ldots, X_n), \| \cdot \|_h)$ into $(L^2(X_1 \times X_n), \| \cdot \|_{op})$ that is, if there exists $C > 0$ such that $\|S_{\varphi}(F)\|_{op} \leq C\|F\|_h$, for all $F \in \Gamma(X_1, \ldots, X_n)$, then we say that $\varphi$ is a Schur multiplier or simply a Schur multiplier, if the measures are clear from the context. The smallest constant $C$ with this property will be denoted by $\|\varphi\|_m$.

We note also that if $H_i = L^2(X_i)$, $D_i = \{ M_\psi : \psi \in L^\infty(X_i) \}$, $i = 1, \ldots, n$, and

$$\hat{S}_\varphi : C_2(H_1, H_2) \times \cdots \times C_2(H_{n-1}, H_n) \to C_2(H_1, H_n)$$

is the map defined by $\hat{S}_\varphi(T_{f_1}, \ldots, T_{f_{n-1}}) = TS_{\varphi}(f_1, \ldots, f_{n-1})$, then if $\varphi(x) \in L^\infty(X_i)$, $i = 1, \ldots, n$, and $\varphi(x_1, \ldots, x_n) = a_1(x_1) \cdots a_n(x_n)$, we obtain

$$\hat{S}_\varphi(T_{f_1}, \ldots, T_{f_{n-1}}) = M_{a_n}T_{f_{n-1}}M_{a_{n-1}} \cdots T_{f_1}M_{a_1}.$$ 

Next theorem generalizes Theorem 2.1 to the multidimensional case giving a characterisation of all Schur multipliers in $L^\infty(X_1 \times \cdots \times X_n)$.

**Theorem 4.2.** Let $\varphi \in L^\infty(X_1 \times \cdots \times X_n)$. The following are equivalent:

(i) $\varphi$ is a Schur multiplier and $\|\varphi\|_m < C$;

(ii) there exist essentially bounded functions $a_1 : X_1 \to M_{\infty, 1}$, $a_n : X_n \to M_{1, \infty}$ and $a_i : X_i \to M_{\infty}$, $i = 2, \ldots, n-1$, such that, for almost all $x_1, \ldots, x_n$ we have

$$\varphi(x_1, \ldots, x_n) = a_n(x_n)a_{n-1}(x_{n-1}) \cdots a_1(x_1) \quad \text{and} \quad \operatorname{esssup}_{x_i \in X_i} \prod_{i=1}^n \|a_i(x_i)\| < C.$$ 

The proof is based on the fact that if $\varphi$ is a Schur multiplier then $\hat{S}_\varphi$ gives rise to a multilinear map from $\mathcal{B}(H_{n-1}, H_n) \times \cdots \times \mathcal{B}(H_1, H_2)$ into $\mathcal{B}(H_1, H_n)$ which is completely bounded, normal and $D_n, \ldots, D_1$-modular, and a characterisation of such maps given by Christensen and Sinclair [11].

The space of all functions satisfying condition (ii) of Theorem 4.2 can be identified with the extended Haagerup tensor product $L^\infty(X_1) \otimes_{eh} \cdots \otimes_{eh} L^\infty(X_n)$ which will be discussed later.

In a same way two dimensional Schur multipliers are related to double operator integrals, multidimensional Schur multipliers are related to multiple operator integrals studied recently by Peller in [32]. This notion is important due to its application to the study of higher order differentiability of functions of operators.

To define multiple operator integrals we fix spectral measures $E_1(\cdot), \ldots, E_n(\cdot)$ on $X_1, \ldots, X_n$, respectively. Let $\mu_1, \ldots, \mu_n$ be scalar measures equivalent to $E_1, \ldots, E_n$, respectively. Consider the space of all functions $\varphi$ for
which there exists a measure space \((T, \nu)\) and measurable functions \(g_i\) on \(X_i \times T\) such that
\[
\varphi(x_1, \ldots, x_n) = \int_T g_1(x_1, t) \cdots g_n(x_n, t) d\nu(t),
\]
for almost all \(x_1, \ldots, x_n\), where
\[
\int_T \|g_1(\cdot, t)\|_\infty \cdots \|g_n(\cdot, t)\|_\infty d\nu(t) < \infty.
\]
The space is called the integral projective tensor product of \(L^\infty(X_1), \ldots, L^\infty(X_n)\) and denoted by \(L^\infty(X_1) \hat{\otimes} \cdots \hat{\otimes} L^\infty(X_n)\).

In the case \(n = 2\) this space coincides with the space of all Schur multipliers by [31]. For \(n > 2\) we can only show that the space consists of Schur multipliers.

For \(\varphi \in L^\infty(X_1) \hat{\otimes} \cdots \hat{\otimes} L^\infty(X_n)\) and \((n - 1)\)-tuple of bounded operators \((T_1, \ldots, T_{n-1})\) Peller defines a multiple operator integral by
\[
I_\varphi(T_1, \ldots, T_{n-1}) = \int_T (\int_{X_1} g_1(x_1, t) dE_1(x_1)) T_1 (\int_{X_2} g_2(x_2, t) dE_2(x_2)) T_2 \cdots T_{n-1}(\int_{X_n} g_n(x_n, t) dE_n(x_n)) d\nu(t).
\]
If the spectral measures are multiplicity free and \(T_1, \ldots, T_{n-1}\) are Hilbert-Schmidt operators with respective kernels \(f_1, \ldots, f_{n-1}\) then one can easily see that \(I_\varphi(T_1, \ldots, T_n)\) is a Hilbert-Schmidt operator with kernel \(S_\varphi(f_1 \otimes \cdots \otimes f_n)\).

Like measurable Schur multipliers, operator multipliers defined by Kissin and Shulman can be generalised to the multidimensional setting.

Let \(H_1, \ldots, H_n\) be Hilbert spaces (\(n\) is even) and let \(H = H_1 \otimes \cdots \otimes H_n\). We define a Hilbert space \(HS(H_1, \ldots, H_n)\) isometrically isomorphic to \(H\): we let \(HS(H_1, H_2) = C_2(H_1^d, H_2)\), and by induction define
\[
HS(H_1, \ldots, H_n) = C_2(HS(H_2, H_3)^d, HS(H_1, H_4, \ldots)).
\]
Let \(\theta : H \otimes K \to C_2(H^d, K)\) be the natural surjective isometry from the product of Hilbert spaces \(H \otimes K\) to the Hilbert space \(C_2(H^d, K)\) of Hilbert-Schmidt operators defined in Section 3. We extend this map by induction to the multidimensional case to get a map \(\theta : H \to HS(H_1, \ldots, H_n)\) by letting
\[
\theta(\xi_{2,3} \otimes \xi) = \theta(\theta(\xi_{2,3}) \otimes \theta(\xi)),
\]
where \(\xi_{2,3} \in H_2 \otimes H_3\) and \(\xi \in H_1 \otimes H_4 \otimes \cdots \otimes H_n\).

Let \(\Gamma(H_1, \ldots, H_n) = (H_1 \otimes H_2) \otimes (H_2 \otimes H_3^d) \otimes \cdots \otimes (H_{n-1} \otimes H_n)\) equipped with the Haagerup norm \(\| \cdot \|_h\) where \(H_1 \otimes H_{i+1}\) is given the operator space structure opposite to the one arising from the embedding \(\theta : H_i \otimes H_{i+1} \hookrightarrow B(H_i^d, H_{i+1})\) (and similarly for \((H_i \otimes H_{i+1})^d = H_i^d \otimes H_{i+1}^d\)).
Fix $\varphi \in B(H)$. We define a mapping $S_\varphi : \Gamma(H_1, \ldots, H_n) \to B(H_1^d, H_n)$ as follows: if $\zeta \in \Gamma(H_1, \ldots, H_n)$ is an elementary tensor, namely,
\[
\zeta = \xi_{1,2} \otimes \eta_{2,3}^d \otimes \xi_{3,4} \otimes \cdots \otimes \xi_{n-1,n},
\]
we let
\[
S_\varphi(\zeta) = \theta(\varphi(\xi_{1,2} \otimes \cdots \otimes \xi_{n-1,n})(\theta(\eta_{2,3}^d)) \cdots (\theta(\eta_{n-2,n-1}^d))).
\]

Using the natural identification, we consider $S_\varphi$ as a map from $C_2(H_1^d, H_2) \circ \cdots \circ C_2(H_{n-1}^d, H_n)$ into $B(H_1^d, H_n)$ which in particular satisfies the following:
\[
S_{a_1 \otimes \cdots \otimes a_n}(T_1 \otimes \cdots \otimes T_{n-1}) = a_nT_{n-1} \cdots a_3T_2a_2T_1a_1^d
\]
for any $a_1 \otimes \cdots \otimes a_n \in B(H)$.

For odd $n$, a similar definition can be given by “adding” to $H_1, \ldots, H_n$ the one-dimensional Hilbert space $\mathbb{C}$. For technical simplicity from now on we restrict our attention to the case of even $n$ and refer the reader to [25, 26] for the general case.

We call $\varphi$ a **concrete operator multiplier** if there exists $C > 0$ such that
\[
\|S_\varphi(\zeta)\|_\text{op} \leq C\|\zeta\|_h, \quad \text{for all } \zeta \in \Gamma(H_1, \ldots, H_n).
\]

As in the two dimensional case, we want to specify classes of “continuous” operator multipliers. Let $A_i$ be a C*-algebra and $\pi_i : A_i \to B(H_i)$ be a representation, $i = 1, \ldots, n$. An element $\varphi \in A_1 \otimes \cdots \otimes A_n$ is called an operator $\pi_1, \ldots, \pi_n$-multiplier if $(\pi_1 \otimes \cdots \otimes \pi_n)(\varphi)$ is a concrete operator multiplier. We denote the set of all $(\pi_1, \ldots, \pi_n)$-multipliers by $\mathfrak{M}_{\pi_1, \ldots, \pi_n}$ and denote by $\|\varphi\|_{\pi_1, \ldots, \pi_n}$ the concrete multiplier norm.

In analogy with the two-dimensional case we say that $\varphi$ is a **universal operator multiplier** if it is $\pi_1, \ldots, \pi_n$-multiplier for all choices of $\pi_1, \ldots, \pi_n$. In this case,
\[
\|\varphi\|_\text{m} \overset{\text{def}}{=} \sup \|\varphi\|_{\pi_1, \ldots, \pi_n} < \infty.
\]

By $\mathfrak{M}(A_1, \ldots, A_n)$ we will denote the set of all universal operator multipliers. For $n = 2$ one obtains the notion of operator multipliers introduced by Kissin and Shulman and discussed in Section 3. Moreover, natural analogs of the Comparision Theorem 3.1 and Corollary 3.2 hold in the new multidimensional setting.

As one may expect, multidimensional operator multipliers are related to completely bounded multilinear maps. We now recall the definition and some related notions.

Let $\mathcal{E}, \mathcal{E}_1, \ldots, \mathcal{E}_n$ be closed subspaces of $B(H), B(H_1), \ldots, B(H_n)$, respectively. We denote by $\mathcal{E}_1 \circ \cdots \circ \mathcal{E}_n$ the algebraic tensor product of $\mathcal{E}_1, \ldots, \mathcal{E}_n$. Let $a_k = (a_{i,j}^k) \in M_{m_k, m_{k+1}}(\mathcal{E}_k), k = 1, \ldots, n$. We denote by
\[
a^1 \circ \cdots \circ a^n \in M_{m_1, m_{n+1}}(\mathcal{E}_1 \circ \cdots \circ \mathcal{E}_n)
\]
the matrix whose $i,j$-entry is
\begin{equation}
\sum_{i_2,\ldots,i_n} a^1_{i_1,i_2} \otimes a^2_{i_2,i_3} \otimes \cdots \otimes a^n_{i_n,j}.
\end{equation}

Let $\Phi : \mathcal{E}_1 \times \cdots \times \mathcal{E}_n \to \mathcal{E}$ be a multilinear map and
\[
\Phi^{(m)} : M_m(\mathcal{E}_1) \times M_m(\mathcal{E}_2) \times \cdots \times M_m(\mathcal{E}_n) \to M_m(\mathcal{E})
\]
be the multilinear map given by
\begin{equation}
\Phi^{(m)}(a^1, \ldots, a^n)_{i,j} = \sum_{i_2,\ldots,i_n} \Phi(a^1_{i_1,i_2}, a^2_{i_2,i_3}, \ldots, a^n_{i_n,j}),
\end{equation}
where $a^k = (a^k_{i,j}) \in M_m(\mathcal{E}_k)$, $1 \leq i,j \leq m$. The map $\Phi$ is called completely bounded if there exists $C > 0$ such that for all $m \in \mathbb{N}$ and all elements $a^k \in M_m(\mathcal{E}_k)$, $k = 1, \ldots, n$, we have
\[
\|\Phi^{(m)}(a^1, \ldots, a^n)\| \leq C\|a^1\| \cdots \|a^n\|.
\]

Every completely bounded multilinear map $\Phi : \mathcal{E}_1 \times \cdots \times \mathcal{E}_n \to \mathcal{E}$ gives rise to a completely bounded linear map from the Haagerup tensor product $\mathcal{E}_1 \otimes_c \cdots \otimes_c \mathcal{E}_n$ into $\mathcal{E}$.

The extended Haagerup tensor product $\mathcal{E}_1 \otimes_{ch} \cdots \otimes_{ch} \mathcal{E}_n$ is defined in [17] as the space of all normal (in each variable) completely bounded maps $u : \mathcal{E}_1^* \times \cdots \times \mathcal{E}_n^* \to \mathbb{C}$. It was shown in [17] that if $u \in \mathcal{E}_1 \otimes_{ch} \cdots \otimes_{ch} \mathcal{E}_n$ then there exist index sets $J_1, J_2, \ldots, J_{n-1}$ and matrices $a^1 = (a^1_{i,s}) \in M_{1,J_1}(\mathcal{E}_1)$, $a^2 = (a^2_{s,t}) \in M_{J_1,J_2}(\mathcal{E}_2)$, \ldots, $a^n = (a^n_{i,t}) \in M_{J_{n-1},1}(\mathcal{E}_n)$ such that if $f_i \in \mathcal{E}_i^*$, $i = 1, \ldots, n$, then
\begin{equation}
\langle u, f_1 \otimes \cdots \otimes f_n \rangle \overset{\text{def}}{=} u(f_1, \ldots, f_n) = \langle a^1, f_1 \rangle \cdots \langle a^n, f_n \rangle,
\end{equation}
where $\langle a^k, f_k \rangle = \langle f_k(a^k_{s,t}) \rangle_{s,t}$ and the product of the (possibly infinite) matrices in (12) is defined to be the limit of the sums
\[\sum_{i_1 \in F_1, \ldots, i_{n-1} \in F_{n-1}} f_1(a^1_{i_1,i_1}) f_2(a^2_{i_1,i_2}) \cdots f_n(a^n_{i_{n-1},i_{n-1}})\]
along the net $\{ (F_1 \times \cdots \times F_{n-1}) : F_j \subseteq J_j \text{ finite}, 1 \leq j \leq n-1 \}$.

We identify $u$ with the matrix product $a^1 \otimes \cdots \otimes a^n$; two elements $a^1 \otimes \cdots \otimes a^n$ and $\tilde{a}^1 \otimes \cdots \otimes \tilde{a}^n$ coincide if $\langle a^1, f_1 \rangle \cdots \langle a^n, f_n \rangle = \langle \tilde{a}^1, f_1 \rangle \cdots \langle \tilde{a}^n, f_n \rangle$ for all $f_i \in \mathcal{E}_i^*$, $i = 1, \ldots, n$. Moreover,
\[\|u\|_{ch} = \inf\{ \|a^1\| \cdots \|a^n\| : u = a^1 \otimes \cdots \otimes a^n \}.
\]

There is a natural bijection $\gamma$ between the extended Haagerup tensor product $\mathcal{B}(H_1) \otimes_{ch} \cdots \otimes_{ch} \mathcal{B}(H_n)$ and the space of multilinear normal completely bounded maps from $\mathcal{B}(H_2, H_1) \times \cdots \times \mathcal{B}(H_n, H_{n-1})$ to $\mathcal{B}(H_n, H_1)$ given as follows: if $u = A_1 \circ \cdots \circ A_n \in \mathcal{B}(H_1) \otimes_{ch} \cdots \otimes_{ch} \mathcal{B}(H_n)$ then
\[
\gamma(u)(T_1, \ldots, T_{n-1}) = A_1(T_1 \otimes I) A_2 \circ \cdots \circ A_{n-1}(T_{n-1} \otimes I) A_n,
\]
for all $T_i \in \mathcal{B}(H_{i+1}, H_i)$, $i = 1, \ldots, n - 1$. This is due to Christensen and Sinclair [11].
The connection of multilinear completely bounded maps with universal multidimensional operator multipliers arises as follows. Let $A_i$ be a $C^*$-algebra, $i = 1, \ldots, n$, and $\varphi \in \mathcal{M}(A_1, \ldots, A_n)$. Then the map $S_{\varphi}$ is completely bounded for the opposite operator space structures, and hence has a completely bounded extension to a map

$$\Phi_{\varphi} : (K(H^d_{n-1}, H_n) \otimes_h \cdots \otimes_h K(H^d_1, H_2), \| \cdot \|_h) \rightarrow (K(H^d_1, H_n), \| \cdot \|_{op})$$

given by

$$\Phi_{\varphi}(T_{n-1} \otimes \cdots \otimes T_1) = S_{\varphi}(T_1 \otimes \cdots \otimes T_{n-1}).$$

Thus, $\Phi_{\varphi}$ is a completely bounded normal map, and the $(A'_n, (A^d_{n-1})', \ldots, (A^d_1)')$-modularity of $\Phi_{\varphi}$ allows then to define a symbol of a multidimensional universal multiplier:

**Theorem 4.3.** Let $A_1, \ldots, A_n$ be $C^*$-algebras and $\varphi \in M(A_1, \ldots, A_n)$. There exists a unique element $u_{\varphi} \in A_n \otimes_{eh} A^d_{n-1} \otimes_{eh} \cdots \otimes_{eh} A_2 \otimes_{eh} A^d_1$ with the property that if $\pi_i$ is a representation of $A_i$ for $i = 1, \ldots, n$ then the map $\Phi_{\pi_1, \ldots, \pi_n(\varphi)}$ coincides with the restriction of $\gamma(\pi_n \otimes_{eh} \pi^d_{n-1} \otimes_{eh} \cdots \otimes_{eh} \pi^d_1(u_{\varphi}))$.

The map $\varphi \rightarrow u_{\varphi}$ is linear and if $a_i \in A_i$, $i = 1, \ldots, n$ then $u_{a_1 \otimes \cdots \otimes a_n} = a_n \otimes a^d_{n-1} \otimes \cdots \otimes a^d_1$. Moreover, $\| \varphi \|_m = \| u_{\varphi} \|_{eh}$.

The notion of completely compact map, completely compact and compact multipliers has natural extensions to the multidimensional case. Namely, if $Y, X_1, \ldots, X_n$ are operator spaces and $\Phi : X_1 \times \cdots \times X_n \rightarrow Y$ is a completely bounded multilinear map, we call $\Phi$ completely compact if for each $\epsilon > 0$ there exists a finite dimensional subspace $F \subseteq Y$ such that

$$\text{dist}(\Phi^{(m)}(x_1, \ldots, x_n), M_m(F)) < \epsilon,$$

for all $x_i \in M_m(X_i)$, $\| x_i \| \leq 1$, $i = 1, \ldots, n$, and all $m \in \mathbb{N}$. We denote by $CC(X_1 \times \cdots \times X_n, Y)$ the space of all completely bounded completely compact multilinear maps from $X_1 \times \cdots \times X_n$ into $Y$.

Let $A_i$ be a $C^*$-algebra, $i = 1, \ldots, n$. We define $\mathcal{M}_{cc}(A_1, \ldots, A_n)$ (resp. $\mathcal{M}_{ff}(A_1, \ldots, A_n)$) as the set of all $\varphi \in \mathcal{M}(A_1, \ldots, A_n)$ such that there exist faithful representations $\pi_1, \ldots, \pi_n$ of $A_1, \ldots, A_n$ with the property that if $\pi = \pi_1 \otimes \cdots \otimes \pi_n$ then $\Phi_{\pi(\varphi)}$ is completely compact (resp. $\Phi_{\pi(\varphi)}$ is compact and the range of $\Phi_{\pi(\varphi)}$ is a finite dimensional space of finite-rank operators).

Let

$$\mathcal{K}_h \overset{\text{def}}{=} K(H_2, H_1) \otimes_h \cdots \otimes_h K(H_n, H_{n-1}).$$

Saar’s result (Theorem 3.7) has the following generalisation:

**Theorem 4.4.** The operator space $\mathcal{E} \overset{\text{def}}{=} K(H_1) \otimes_h (B(H_2) \otimes_{eh} \cdots \otimes_{eh} B(H_{n-1})) \otimes_h K(H_n)$ is isometrically isomorphic to $\mathcal{F} \overset{\text{def}}{=} CC(\mathcal{K}_h, K(H_n, H_1))$ with an isometry given by the restriction of $\gamma$ to $\mathcal{E}$.

This leads to the following characterisation of completely compact universal multipliers in terms of their symbols:
Theorem 4.5. Let $A_1, \ldots, A_n$ be $C^*$-algebras and $\varphi \in M(A_1, \ldots, A_n)$. The following are equivalent:

(i) $\varphi \in M_{cc}(A_1, \ldots, A_n)$;

(ii) $u_\varphi \in K(A_n) \otimes_h (A_n^{\circ-1} \otimes_{eh} \cdots \otimes_{eh} A_2) \otimes_h K(A_1^{\circ})$

(iii) there exists a net $\{\varphi_\alpha\}_\alpha \subseteq M_{ff}(A_1, \ldots, A_n)$ such that $\|\varphi_\alpha - \varphi\|_m \to 0$.

The important point to note here is that there is no direct analogy with the two-dimensional case: the space $CC(K_h, K(H_n, H_1))$ is not isometrically isomorphic to $K(H_1) \otimes_h K(H_2) \otimes_h \cdots \otimes_h K(H_n)$, and the symbol of a completely compact map maybe an element of a bigger than $K(A_n) \otimes_h K(A_n^{\circ-1}) \otimes_h \cdots \otimes_h K(A_1^{\circ})$ space contrary to what one may expect by following the analogy with the two-dimensional case.

The property of the set of universal completely compact multipliers in $A_1 \otimes \cdots \otimes A_n$ to coincide with the set of compact universal multipliers depends only on the structure of compact elements of $A_1$ and $A_n$ and not on $A_k$, $k = 2, \ldots, n - 1$. The condition on $K(A_1)$ and $K(A_n)$ are exactly the ones given in Theorem 3.9.

We shall end the section by describing an application of multidimensional Schur multipliers to abstract harmonic analysis. Let $G$ be a locally compact, $\sigma$-compact group and let $A(G)$ be the Fourier algebra of $G$. We recall that $\lambda_x$ denote the left regular representation of $G$ on $L^2(G)$. Since $A(G)$ is the predual of the von Neumann algebra $VN(G)$, it possesses a canonical operator structure. Therefore we can define the multidimensional Fourier algebra as follows:

$$A^n(G) = \frac{A(G) \otimes_{eh} \cdots \otimes_{eh} A(G)}{n}.$$ 

Since $VN(G)$ is generated by $\lambda_x$, $x \in G$, it follows from the definition that the elements of $A^n(G)$ can be identified with functions $f \in L^\infty(G^n)$ given by $f(x_n, \ldots, x_1) = \Phi(\lambda_{x_n} \cdot \cdots \cdot \lambda_{x_1})$, where $\Phi : VN(G) \times \cdots \times VN(G) \to \mathbb{C}$ is a normal completely bounded multilinear map.

For $f \in A(G)$ we define a map $\theta : A(G) \to A^n(G)$ by

$$\theta(f)(x_n, \ldots, x_1) = f(x_n \ldots x_1).$$

We call a function $\varphi \in L^\infty(G^n)$ an $n$-multiplier of $A(G)$ if $\varphi \theta(f) \in A^n(G)$ whenever $f \in A(G)$. We call $\varphi$ a completely bounded $n$-multiplier if the mapping $f \mapsto \varphi \theta(f)$ is completely bounded. The following characterisation, which is a multidimensional version of Theorem 2.6, was established in [39].

Theorem 4.6. Let $\varphi \in L^\infty(G^n)$. The following are equivalent:

(i) $\varphi$ is a completely bounded $n$-multiplier;

(ii) The function $\tilde{\varphi} \in L^\infty(G^{n+1})$ given by

$$\tilde{\varphi}(x_1, \ldots, x_n) = \varphi(x_{n+1}^{-1} x_n, \ldots, x_2^{-1} x_1)$$

is a Schur multiplier with respect to the left Haar measure.
