

Partial Peace: Rebel Groups Inside and Outside of Civil War Settlements*

DESIRÉE NILSSON

Department of Peace and Conflict Research, Uppsala University

Previous research proposes that peace is more likely to become durable if all rebel groups are included in the settlement reached. The argument implies that if actors are excluded and continue to pursue the military course, this could have a destabilizing effect on the actors that have signed an agreement. This article argues that all-inclusive peace deals – signed by the government and all rebel groups – are not the panacea for peace that many seem to believe. Given that the parties are strategic actors who are forward-looking when making their decisions, the signatories should anticipate that the excluded parties may continue to fight. Therefore, the risk of violent challenges from outside actors is likely to already be factored into the decisionmaking calculus when the signatories decide to reach a deal, and so does not affect their commitment to peace. Implications from this theoretical argument are tested using unique data on the conflict behavior of the government and each of the rebel groups in internal armed conflicts during the post-Cold War period. The results are well in line with the theoretical expectations and show that whether an agreement leaves out some actor does not affect whether the signatories stick to peace. The results demonstrate that, even when excluded rebel groups engage in conflict, this does not affect the signatories' commitment to peace. Hence, the findings suggest that partial peace is possible.

Introduction

A potential obstacle to durable peace, and an empirical reality of many civil wars, is that conflicts often involve numerous rebel groups. Cases in point are, for instance, Bosnia and Herzegovina, Burundi, Colombia, the Democratic Republic of Congo, and Sudan. Some scholars hold that if a peace agreement includes all the warring parties, peace is more likely to prevail (e.g. Hampson, 1996; Rubin, 2002). For instance, Licklider (2001: 701)

stresses the importance of inclusiveness and points out that third parties 'should exert every effort to bring all of the important players into the process as soon as possible'. The argument implies that the presence of excluded parties can jeopardize peace, not only by heightening the risk of violence involving the outside actors, but also by influencing the commitment to peace among the signatories. However, while many seem to expect that all-inclusive peace agreements are more likely to see peace prevail, this claim has so far not been

* I would like to thank Guest Editors Håvard Hegre, Gary Milante, and Ibrahim Elbadawi, three anonymous reviewers, and colleagues at the Department of Peace and Conflict Research, Uppsala University, in particular, Mats Hammarström, Margareta Sollenberg, Hanne Fjelde, Lisa Hultman, Isak Svensson, Anna Jarstad, and Erik Melander, for excellent comments and suggestions. The research was

supported by the World Bank research project on 'Political Institutions, Development, and Domestic Civil Peace', funded by the government of Norway. The replication data and a web appendix are available at <http://www.prio.no/jpr/datasets>. For recent versions of the UCDP data used here, see <http://www.ucdp.uu.se>. examined in a quantitative study. The present study addresses this lacuna in previous research by providing a first test of this proposition. Hence, the *purpose* of this article is to explore whether all-inclusive peace agreements are more likely to provide durable peace than partial agreements that leave out one or more rebel groups.

I argue that all-inclusive peace deals are not the panacea for peace that many seem to believe. If we think of parties in civil wars as strategic actors that look ahead when they make decisions, we can expect that the signatories have considered the possibility that excluded parties may continue to engage in armed conflict. Thus, the risk of violent challenges from outside actors is likely to already be factored into the decisionmaking calculus when the signatories decide to reach a deal. This suggests that, while the excluded actors may continue to fight, settlements leaving out one or more rebel groups should not necessarily make the signatories any more likely to engage in violence.

Implications from this theoretical argument are tested using unique data from the Uppsala Conflict Data Program (UCDP) on the conflict behavior of the government and each of the rebel groups in internal armed conflicts, 1989–2004. The statistical analysis is conducted employing a Cox proportional hazards model. The results are well in line with the theoretical argument. The findings show that whether an agreement leaves out one or more rebel groups does not affect whether the signatories stick to peace. At the same time, agreements that exclude some party are found to reduce the overall prospects for peace in the conflict, that is, when taking into account the conflict behavior of both signatories and non-signatories. Moreover, the results demonstrate that outside actors are more likely to engage in post-settlement violence than the signatories. Importantly, the findings show that, even if

parties are excluded and continue to fight, this does not affect the signatories' commitment to peace. Hence, the results indicate that partial peace is possible.

Previous Research

The amount of scholarly work devoted to the issue of how to end conflicts and move towards durable peace has increased in recent years (e.g. Fortna, 2003, 2004; Hartzell & Hoddie, 2003; Jarstad & Nilsson, in press; Walter, 1999, 2002b). However, while this field has seen significant advances, the literature on durable peace suffers from an unfortunate disconnect between the qualitative and quantitative research. Many case studies recognize that the rebel side often consists of several actors and propose that various aspects such as spoiler dynamics can have implications for creating a lasting peace (e.g. Hampson, 1996; Stedman, 1997). Whereas case studies within the literature on durable peace emphasize that a refined view of the rebel side is needed, quantitative studies have, so far, mainly focused on two parties – the government and the opposition.¹

To examine the question of whether to include all actors in peace agreements, as well as other pertinent issues, it is necessary to move beyond a characterization of civil war as involving only two parties. Indeed, by recognizing that civil wars often consist of multiple actors, we can begin to incorporate insights from case studies into our analyses of global patterns.

This article addresses the claim in the case study literature that, in order to ensure durable peace, it is essential that *all* parties

¹ There are some studies that do incorporate some aspects pertaining to the rebel side, but these do not explore the dyadic interactions of the government and each rebel group, which forms a significant part of the present study (e.g. Doyle & Sambanis, 2000; Fortna, 2003; Hoddie & Hartzell, 2003).

are included in the settlement. Indeed, a key hypothesis is that an inclusive agreement, in which all actors with the potential to resume hostilities take part, is more likely to provide a sustainable solution (Ohlson & Söderberg, 2002). Hampson (1996: 217), for instance, argues that

it is absolutely essential that all the warring parties have a seat at the negotiation table and are directly involved in discussions about the new constitutional and political order that will be created after the fighting stops. A 'good' agreement is one that has been crafted by all parties to the conflict. If parties are excluded from these negotiations, or if their interests are not represented at the bargaining table, they will have a much stronger incentive to defect from the peace process and resort to violence to achieve their aims.

Licklider (2001: 701) also argues in favor of inclusive peace agreements and stresses that third parties should try to get all of the important players into the agreement and 'resist the temptation to settle for an easy agreement with moderates, ... because such settlements are very likely to fail'. Moreover, according to Rubin (2002: 100), actors on the outside of an agreement may try to disrupt an agreement reached. He suggests that

one should probably attempt to include in negotiations all parties who are in a position to disrupt whatever settlement is arrived at; it may be more difficult to reach agreement with many parties and issues floating around, but if an agreement is reached under these circumstances, it will have a greater chance of surviving.

Consequently, an agreement that includes all parties to the conflict should be more likely to ensure that peace prevails than a deal where one or several parties are excluded. The mechanisms underlying the argument on inclusiveness are not clearly spelled out, but most of the works on this topic imply that excluded parties can threaten the peace between the signatories. In this context, the literature on spoilers in civil wars is relevant

(Ayres, 2006; Newman & Richmond, 2006; Stedman, 1997; Zahar, 2003).² Indeed, the argument on inclusiveness seems to suggest that, if an actor on the outside continues to pursue the military course, this can have a destabilizing effect on the actors that have signed an agreement.³ Thus, according to previous research, an agreement that leaves out one or more parties should not only increase the risk that excluded parties engage in violent conflict, but also make the signatories more likely to fight.

Signatories Sticking to Peace

The claim that all parties should be included in a peace deal is appealing and seems to make intuitive sense. However, applying insights from bargaining theory, which emphasizes the strategic nature of conflict, calls this into question. The bargaining perspective depicts war and its resolution as a bargaining process, and at the center stage of analysis is the strategic interaction of the parties. The parties are seen to be acting strategically when 'each actor's ability to further its ends depends on how other actors behave, and therefore each actor must take the actions of others into account' (Lake & Powell, 1999: 3). Scholars are increasingly arguing that parties in civil wars are to be seen as strategic actors who are forward-looking and try to anticipate the actions of other actors when making their decisions (e.g. Cetinyan, 2002; Walter, 2006). In this

² Stedman (1997: 5) defines spoilers as 'leaders and parties who believe that peace emerging from negotiations threatens their power, worldview, and interests, and use violence to undermine attempts to achieve it'. Note that the present study treats all warring parties as potential spoilers and, hence, does not focus specifically on spoiler violence.

³ While not explicitly stated in the literature, it is conceivable that not only are the signatories influenced by direct spoiler attacks intended to wreck the peace, but also, for various reasons, it may be more difficult for the signatories to stick to peace if the non-signatories continue to pursue *their* war.

bargaining process between the warring parties, revealing information plays a key role. By engaging in fighting and taking part in negotiations, the parties can reveal information about their reservation price (i.e. the minimum they can accept) and thus facilitate a settlement, instead of fighting a costly war. Whereas some actors may have revealed enough information about their capabilities and resolve in order to reach a bargain, the beliefs of others have not converged (i.e. they have different expectations about the outcome) and have yet to agree on a mutually preferable deal (Fearon, 1995; Filson & Werner, 2002).

Applying these insights, I propose that all-inclusive peace agreements are not necessarily more likely to provide peace than a deal that leaves out some actor. The argument in previous research suggests that settlements that do not include all parties increase the risk that the signatories engage in conflict, primarily as a consequence of violence from the excluded parties. But if we consider that the warring parties are strategic actors that try to anticipate the decisions of all other actors, this yields other expectations. I argue that the signatories, when taking the decision to sign a deal, are trying to anticipate the actions of all actors in the conflict, including rebel groups outside of the peace agreement.

The warring parties that decide to sign an agreement know if there are excluded parties, and presumably they have considered the possibility that the actors on the outside may continue to fight. The fact that the government and the excluded parties are unable to reach a deal suggests that they do not share the same expectation concerning the likely outcome on the battlefield and, hence, will continue to pursue the military course. Still, some parties may have converged expectations without necessarily signing an agreement, and it is also conceivable that an excluded group may have been marginalized because of its insignificance, or may be

weakened as the government redirects its forces against parties outside of an agreement. This could, hence, make violence involving outside actors less likely. However, on average, it is more plausible to expect that excluded parties will engage in violence.

This is not to say that the signatories in civil war are able to anticipate every move by the outside actors. In some instances, the signatories may, for some reason, expect that the non-signatories will refrain from using violence. But, since excluded actors in general are likely to fight, it is probably more common that the signatories expect that outside actors will engage in conflict. Moreover, the argument is not implying that signatories always stick to peace, while the non-signatories do not. Certainly, some signatories may have signed an agreement without having benign intentions, and, even if the signatories do intend to stick to peace, commitment problems may serve to increase the risk of violence.⁴ This said, the non-signatories should probably be more likely to engage in violence following a settlement than the signatories. Hence, the signatories should have a fairly good sense of the violent challenges they may be facing and, therefore, take such a scenario into account when signing the deal.

The fact that this argument calls into question the necessity of all-inclusive deals may at first glance seem discouraging. However, the argument rather implies that there may be many different paths to peace, since the signatories are expected to commit to peace, even if some party is left on the outside. Hence, agreements that exclude some actors may be one way forward when an all-inclusive deal is not possible.

There are several testable implications that follow from my theoretical argument.

⁴ A credible commitment problem can arise when the parties agree on the bargaining range and would like to avoid the costs of war but fear that the other party may renege on the deal. See, for instance, Walter (2002b).

To begin with, focusing on the settlement as such, it is possible to draw out two implications. First, whether a peace agreement is all-inclusive or not is not likely to affect the signatory peace (i.e. whether peace prevails in terms of all the signatories sticking to peace). The second implication is that, since the excluded parties are likely to continue to fight, an agreement that leaves out one or more rebel groups should reduce the overall prospects for peace (i.e. whether peace prevails in the entire conflict, taking into account the conflict behavior of both signatories and non-signatories). In other words, if the agreement fails to include some rebel group, this should not affect whether the signatories stick to peace, but it is likely to reduce the overall prospects for peace, since the non-signatories may engage in conflict.

Furthermore, if we move the analysis to the dyadic interactions between the government and each of the rebel groups, there are some additional implications. The third implication is that the non-signatories, on average, should be more likely to engage in post-settlement violence than the signatories. Fourth, focusing specifically on the signatory dyads, the argument suggests that each of these should not be any more likely to resort to violence if the deal excludes some actor. The fifth and last implication takes this notion of exclusion one step further. Even if the signatories are faced with excluded parties that engage in conflict, we should not expect to see an increase in the risk of signatory violence. By examining these implications from my theoretical argument, this article aims to shed light on the issue of whether all-inclusive peace agreements can affect the prospects for peace.

Research Design

Data

The data are from the Uppsala Conflict Data Program (UCDP) and include all internal

armed conflicts where at least one peace agreement has been signed during the period 1989–2004.⁵ The UCDP defines an internal armed conflict as a contested incompatibility over government and/or territory, between a government and an opposition organization, and which reaches the level of minor armed conflict, that is, at least 25 battle-related deaths in at least one year. The UCDP dataset covering the post-Cold War period is unique in that it includes yearly data on *all* rebel groups involved in an armed conflict with the government that has reached at least this level of battle-deaths. For the purposes of this study, it is necessary to have comparable yearly data on the conflict behavior involving the government and each of the rebel groups. Hence, this dataset will be used.

The internal armed conflicts each consist of one or more dyads, where the government and each rebel group engage in violence reaching the level of 25 battle-related deaths in at least one year. Hence, there may be two or more warring parties, of which one is always the government. In this study, a party that, *prior* to the peace agreement, met the criterion of ‘warring party’ is of interest, and the government and these rebel groups may, or may not, have signed a peace agreement in the conflict. The reason for focusing on the warring parties is that these have been active in the conflict and, at some point, had both the incentives and capabilities to use armed violence.

The UCDP also provides a comprehensive dataset of all peace agreements signed in the post-1989 period. Some other lists of peace agreements focus only on the settlements signed by all, or the major warring

⁵ If not otherwise mentioned, the data in this study come from the UCDP. For definitions of concepts, see UCDP (2006) and Harbom, Högbladh & Wallensteen (2006). Note that, since the conflict behavior of the parties is assessed the year after the signing of a peace agreement, and these data have been available until 2004, only agreements up to 2003 are included in the study.

parties (e.g. Walter, 1999: 127–128; 2002b: 52). For the purposes of this study, it is necessary to include all peace agreements and not merely those signed by certain rebel groups. The dataset from the UCDP includes agreements where only some of the rebel groups are signatories. Hence, this study covers all peace agreements that are signed by the government and one or several rebel groups, and which address the incompatibility by settling all or part of it (UCDP, 2006).⁶ The data used consist in total of 82 peace agreements in 40 internal armed conflicts, and some of the conflicts stand out in terms of the number of agreements signed: for example, in Chad, nine peace agreements were reached in the period under study. Other conflicts, such as the one in Congo-Brazzaville, have seen only one peace agreement during the same period.

Statistical Technique and Structure of the Datasets

The empirical evaluations are conducted using duration analysis. In this case, the interest lies in the duration of peace after the signing of a peace agreement, up to the point where the warring parties may engage in post-settlement armed conflict (i.e. experience an event), if at all. I use a Cox proportional hazards model that has the advantage of not assuming a specific parametric form for its distribution (Cox, 1972).

In an effort to evaluate the issue of inclusiveness as thoroughly as possible, two different datasets have been constructed. One focuses on the settlement level, whereas the other shifts the focus to the dyadic interactions between the government and each rebel group. When analyzing the *settlement* level, the unit of analysis is the post-agreement-year,

whereas the analysis at the *dyadic* level concerns the government and each rebel group, and the unit of analysis is the post-agreement-dyad-year. In the dyadic dataset, there may be several dyads in a conflict, where the government remains the same in each dyad.

In both datasets, the peace agreements and dyads, respectively, are at risk of experiencing an event – that is, armed conflict involving a government and a rebel group that results in at least 25 battle-related deaths in a year – from the year after the signing of an agreement until the observation period ends on 31 December 2004.⁷ The first dataset consists of 82 peace agreements, and, in the dyadic dataset, there are in total 84 dyads that may or may not have signed one or more settlements. Since some of the variables vary over time, models with time-varying covariates are used for both sets of data, which makes it possible to study changes over time. This means that there are multiple observations for each of the settlements and dyads, respectively.

In the dyadic dataset, the dyads run the risk of experiencing post-settlement armed conflict after each of the agreements (if there are several signed in the conflict).⁸ Thus, in this dataset, the dyads may exit the risk set if they experience armed conflict following a settlement, and then re-enter on the condition that a new settlement is reached. Note

⁶ In line with previous research, I do not study ‘peace process agreements’, since these are merely ‘outlining a process for regulating or resolving the incompatibility’ (UCDP, 2006).

⁷ The primary focus is on the parties that were active prior to the signing of the agreement, and therefore new parties that later emerge are not taken into account in the main analysis. However, in the analysis at the settlement level, a robustness check is conducted using an alternative dependent variable that captures the conflict behavior of new parties too.

⁸ Some dyads drop out of the data earlier, either because the incompatibility is resolved or because they cease to exist. For instance, if a rebel group completely dissolves or takes over the government, the dyad drops out of the dataset. Based on information in the Uppsala Conflict Database, each of the parties in the dataset was evaluated according to these criteria, in order to determine whether the dyad should continue to remain under observation (UCDP, 2006).

that whenever a settlement is reached by any of the rebel groups in the conflict, the settlement becomes analytically relevant for all dyads in the conflict, regardless of whether these are signatories or not. Some of the dyads may engage in post-settlement violence more than once. For example, in the conflict between the Israelis and the Palestinians, several peace agreements have been signed, and the non-signatory Hamas have engaged in violence with the Israeli government following more than one of these agreements. Hence, I employ a duration model that can handle such repeated events.⁹

Dependent Variables

The post-settlement period is often more complex than peace simply prevailing or breaking down, so it is important that our dependent variables reflect what a durable peace may entail. Given that the signatories as well as the non-signatories may use violence after an agreement has been signed, it is important to take into account both these dimensions of peace duration.¹⁰ Since the unit of analysis is different for the two sets of data, the dependent variables used for the settlement and dyadic level are not the same.

In the analysis at the settlement level, two dependent variables are employed, in order to capture different dimensions of peace duration, that is, the signatories' commitment to peace and the overall peace duration in the conflict. The variable *signatory peace duration* measures the number of years of peace from the signing of the agreement until the government and at least one of the other signatories engage in violence, or, if peace has prevailed,

to the end of the observation period.¹¹ Hence, this variable focuses on the behavior of the signatories to the agreement. To exemplify, in Colombia, the peace agreement, signed between the government and EPL (People's Liberation Army) in 1991, was not followed by armed conflict between the signatories until years later when, in 2004, the fighting between the government and EPL again reached the level of minor armed conflict.¹² Meanwhile, FARC-EP (Revolutionary Armed Forces of Colombia – People's Army) and ELN (National Liberation Army), who did not sign the peace agreement, continued to fight. But since this variable is intended to capture only the conflict behavior of the signatories, this means that, in terms of the signatory peace duration, peace prevailed for 13 years.

In contrast, the variable *overall peace duration* takes into account the conflict behavior of the government, the other signatories to the agreement, and the non-signatories, that is, the warring parties that were standing outside of the deal. This variable is measured as the number of years of peace from the signing of the agreement until either a signatory or a non-signatory becomes involved in armed conflict or, if peace has prevailed, to the end of the observation period. Again, taking the example of Colombia, the fact that the government and FARC-EP and ELN continued to fight is captured by this variable. Thus, whereas peace prevailed in Colombia for 13 years in terms of the signatory peace duration, the overall peace duration broke down immediately, as the

⁹ More specifically, I use a conditional gap time model, see Box-Steffensmeier & Jones (2004: 159–161).

¹⁰ It can be the government or any of the rebel groups that is the first to return to armed conflict after an agreement. While this is an interesting aspect to consider, the data used here do not make it possible to determine which actor first resorts to violence.

¹¹ Occasionally, there are several peace agreements reached in the same conflict. Of these, there are a few in which the signatories to the settlement already are at peace when they decide to reach another peace agreement. To avoid overestimating the impact of these agreements on peace duration, the subsequent agreement is seen as replacing the previous one.

¹² Some minor incidents were reported at various occasions during this period, but the violence concerning EPL did not reach 25 battle-related deaths in any given year until 2004, when it reached that level.

non-signatories FARC-EP and ELN continued their struggle.

In the analysis at the dyadic level, the dependent variable measures the conflict behavior of the government and a particular rebel group. The variable *dyadic peace duration* captures whether the dyad, consisting of a government and a rebel group, was engaged in armed conflict, from the signing of a settlement in the conflict to the end of the observation period. Thus, in this case, the conflict behavior is measured for each dyad, and the rebel group may, or may not, be a signatory to a settlement. In Colombia, the dyad consisting of the government and EPL was at peace until 2004, whereas the dyads involving the government and FARC-EP and ELN, respectively, continued to fight and, therefore, had already experienced post-settlement armed conflict at the time of the first observation, that is, the year following the agreement in 1991.

In both datasets, the post-settlement armed conflict is measured as of the year following the peace agreement, to ascertain that the violence has taken place *after* the settlement was signed. While it would have been preferable to measure the dependent variable directly after the signing of a settlement, the fact that it is the yearly accumulation of at least 25 battle-related deaths that is studied makes such an approach unfeasible.¹³

Independent Variables

A key aspect is the rebel groups' inclusion or exclusion in relation to a particular peace agreement. The first variable, *exclusive-multiple*, which is used at the settlement level, is coded 1 if one or more rebel groups are standing on the outside of the deal and 0 otherwise. In order to account for the fact that two-party conflicts are all-inclusive by definition, this variable will be used together with

¹³ The lowest peace duration is therefore one year, although a dyad may engage in conflict immediately after a settlement.

the variable *two-party conflict*, coded 1 if the conflict involves only two parties and coded 0 if the conflict involves three or more actors. By using these variables in the same model, it becomes possible to assess the effect of partial agreements versus all-inclusive agreements in a multiparty context.

In the analysis at the dyadic level, the variable *excluded* refers to a particular rebel group's inclusion or exclusion in relation to a settlement. The variable is coded 1 if the rebel group, in a given year, had not signed a peace agreement and coded 0 if the rebel group had signed a peace agreement, or previously signed a peace agreement and then refrained from using violence.¹⁴ In a subsample of the dyadic dataset covering all the signatories, two other variables concerning exclusion are used. The first variable, *exclusive-peace agreement*, is coded 1 if the dyad was a signatory to a deal that excluded some actor and 0 otherwise. The second variable, *excluded-fight*, is coded 1 if there is one or more excluded parties that in a given year engages in conflict with the government, and, if not, this variable is coded 0.

The control variables in this study include factors that previous research has considered important for peace duration, and that theoretically may affect the independent variables as well as the dependent variables. The control variables are basically the same for both levels of analysis, and where there is a difference, this is pointed out. To begin with, it is essential to control for the number of parties in each conflict, as this potentially can affect the results. The variable *number of parties* measures the number of warring parties that have been

¹⁴ This means that a group that has signed an agreement and then resorted to violence is considered to be a potential signatory to any subsequent peace agreement signed in the incompatibility. Thus, if another peace agreement is signed in the incompatibility and a group remains on the outside of the deal, that group is seen as excluded. Conversely, if a rebel group has signed an agreement and then refrained from using violence during the observation period, it is coded as included in any subsequent agreement.

active in the conflict from 1989 onwards, up until the year in question.

Although the findings are contradictory, previous research has indicated that the duration of the conflict increases the duration of peace, while the intensity of the conflict has been suggested to decrease peace duration (e.g. Doyle & Sambanis, 2000: 787; Fortna, 2004; Hartzell, Hoddie & Rothchild, 2001: 202). In the dataset at the settlement level, the variable *conflict duration* counts the number of years since the conflict first reached the threshold of 25 battle-related deaths (which may be before 1989), up to a given year. In the dyadic dataset, I control for *dyad-conflict duration*, which is measured in the same way but starts counting from the year when a particular dyad first reached this threshold. Furthermore, the variable *conflict intensity* is used at the settlement level and is coded 1 if the conflict (either in the year of observation or previously) reaches the level of war, meaning more than 1,000 battle-related deaths in a year, and is otherwise coded 0. In the dataset at the dyadic level, I include the variable *dyad-conflict intensity*, which is coded in the same fashion as conflict intensity, but this variable instead captures whether a particular dyad has reached the level of war or not. Moreover, whether the conflict concerns a certain territory or power over the government can possibly affect the prospects for peace (e.g. Wallensteen, 2002; Zartman, 1995). Thus, I created a control variable, *conflict issue*, which is coded 1 if the incompatibility is fought over government and 0 if it is fought over territory (UCDP, 2006).

Peacekeeping forces have been found to play a key role in the post-settlement phase by increasing the duration of peace (Fortna, 2003). In addition, it has been proposed that UN peacekeepers may be more 'neutral' than regional peacekeepers (Zahar, 2003: 117). Hence, I control for *UN peacekeeping*, which is coded 1 if a peacekeeping operation led by the United Nations was present in a given year, and 0 otherwise. I also control for *non-*

UN peacekeeping, in order to capture whether other peacekeeping forces than the UN were deployed. This variable is coded like the *UN peacekeeping* variable. For a description of the data used, see Heldt & Wallensteen (2006). Finally, in line with previous research, I control for the type of deal reached, since agreements with power-sharing provisions could be more likely to see peace endure (Hartzell & Hoddie, 2003). Hence, the dummy variable *power-sharing* was coded 1 if the agreement contained at least one pact concerning the sharing of power, that is, military, territorial, or political power, and was otherwise coded 0.¹⁵

Results and Analysis

From my theoretical argument, it was possible to derive five testable implications, and the results from the statistical analysis are presented in Tables I and II.¹⁶ In all models, the hazard ratios are reported, rather than the coefficients. A hazard ratio above 1 increases the risk of post-settlement violence, whereas a value below 1 decreases the risk of post-settlement violence. To exemplify, a hazard ratio of 1.5 means that the risk of peace failing is increased by 50%, and a hazard ratio of 0.7 indicates that the risk of peace failing is decreased by 30%.¹⁷

I begin by examining the implications at the settlement level, and the first implication is assessed by looking at the peace duration for the signatories (*signatory peace duration*). The first expectation that was derived from my argument proposes that whether or not a peace agreement is all-inclusive should not affect the signatories' commitment to peace.

¹⁵ This is coded in line with the definitions in Walter's (2002a) war termination dataset (Nilsson, Svensson & Sundberg, 2006).

¹⁶ For descriptive statistics, see the web appendix.

¹⁷ All statistical analyses are carried out using Stata 10.0 (StataCorp, 2007).

Table I. Inclusive Peace Deals and the Risk of Post-Settlement Conflict: Settlement Level

	<i>Signatory peace duration Model 1</i>	<i>Overall peace duration Model 2</i>
Exclusive-multiple	0.750 (0.93)	1.843** (2.25)
Two-party conflict	0.739 (0.81)	0.786 (0.77)
Conflict duration	0.986 (0.49)	1.028* (1.94)
Conflict intensity	2.433*** (2.69)	1.679** (2.41)
Conflict issue	1.959 (1.56)	1.120 (0.45)
UN peacekeeping	0.840 (0.43)	0.629 (1.22)
Non-UN peacekeeping	0.956 (0.12)	1.288 (0.99)
Power-sharing	0.506* (1.77)	0.515** (2.31)
Observations	295	235
No. of failures	29	45
Log likelihood	-113.281	-184.757

A Cox proportional hazards model is employed. Hazard ratios rather than coefficients are reported, with robust z-statistics (given in parentheses) clustered on conflict. *Statistically significant at the .10 level. **Statistically significant at the .05 level. ***Statistically significant at the .01 level. Two-tailed tests are used. Stata 10.0 was used to generate the statistical results.

The variable *exclusive-multiple* shows the effect of an agreement that leaves out one or more actors versus a deal that includes all actors, in a multiparty context. The results indicate no statistically significant effect of the variable *exclusive-multiple* on the duration of peace for the signatories (Model 1, Table I). Hence, the result is in line with the theoretical argument that the signatories should have considered that the excluded parties might threaten the peace process, therefore not affecting the signatories' commitment to peace. The effect even goes in the opposite direction to previous research, which has suggested that all-inclusive deals increase the prospects for peace. Indeed, if anything, the findings rather indicate that all-inclusive agreements make the signatories

more likely to fight.¹⁸ To see whether it may be sufficient that most, rather than all, of the actors have signed the deal, I estimated a model that includes a variable that captures the proportion between the number of signatories and the number of warring parties to a conflict. But no significant effect could be found.

The second implication focuses on the overall peace, taking into account the conflict behavior of both signatories and non-signatories (*overall peace duration*). The expectation is that an agreement leaving out

¹⁸ One possible interpretation is that some actors that sign an all-inclusive agreement have done so because of outside pressure from a third party, and therefore signatories to such a deal may be more likely to resort to armed conflict (e.g. Werner & Yuen, 2005).

Table II. Exclusion and the Risk of Post-Settlement Conflict: Dyadic Level

	<i>Dyadic peace duration</i> <i>Model 1</i>	<i>Dyadic peace duration (signatories)</i> <i>Model 2</i>	<i>Model 3</i>
Excluded	2.001*** (3.16)		
Exclusive-peace agreement		1.139 (0.31)	
Excluded-fight			1.045 (0.09)
Number of parties	1.144 (1.34)	1.124 (0.59)	1.149 (0.66)
Dyad-conflict duration	0.996 (0.26)	1.013 (0.44)	1.014 (0.46)
Dyad-conflict intensity	1.300 (1.06)	1.027 (0.07)	1.048 (0.13)
Conflict issue	1.724** (2.14)	3.027** (2.01)	2.992** (2.03)
UN peacekeeping	0.599 (1.55)	1.000 (0.00)	0.988 (0.03)
Non-UN peacekeeping	2.050*** (2.84)	2.537*** (2.77)	2.533*** (2.79)
Power-sharing		0.566 (1.33)	0.567 (1.34)
Observations	477	376	376
No. of failures	62	33	33
Log likelihood	-220.280	-104.411	-104.436

A Cox proportional hazards model is employed. Hazard ratios rather than coefficients are reported, with robust z-statistics (given in parentheses) clustered on dyad. *Statistically significant at the .10 level. **Statistically significant at the .05 level. ***Statistically significant at the .01 level. Two-tailed tests are used. Stata 10.0 was used to generate the statistical results.

one or more rebel groups should reduce the overall prospects for peace, since the excluded parties are likely to continue to fight. As can be seen in Model 2, Table I, the variable *exclusive-multiple* has a statistically significant effect at the 0.05 level concerning the overall peace duration, that is, when taking into account the conflict behavior of the signatories, as well as the non-signatories.¹⁹ Hence, the result is in the expected

direction and shows that, if an agreement excludes one or more rebel groups, the risk of post-settlement violence involving either signatories or non-signatories increases by 84%. The fact that that no such effect could be found, when studying the conflict behavior of the signatories, suggests that the prospects of overall peace are reduced, owing to violence involving the non-signatories.²⁰ The results at the settlement level, however, only give us the general picture, and there is,

¹⁹ It can be noted that, in an alternative specification using a linear measure of the number of parties, exclusion is no longer significant but is still in the expected direction. This alternative model, however, cannot, at the same time, account for the fact that agreements in two-party conflicts are all-inclusive by definition, which is an important aspect to consider.

²⁰ This is also in line with the expectation in previous research that all-inclusive deals may increase the prospects for peace, but notably such an effect cannot be found when looking only at the signatories.

hence, a need for a more fine-grained analysis focusing on the interactions between the government and the different rebel groups.

In the analysis at the dyadic level, the focus is on the duration of peace for the government and each of the rebel groups (*dyadic peace duration*).²¹ The third expectation based on my argument stated that, given the signing of a settlement in a conflict, on average, the non-signatories should be more likely to engage in post-settlement violence than the signatories. The findings support this expectation, as the variable *excluded* shows an increase in the risk that a dyad will engage in violence (Model 1, Table II).²² If a rebel group is a non-signatory rather than a signatory, the risk of post-settlement armed conflict doubles, and the result is statistically significant at the 0.01 level. Put differently, if a rebel group has signed an agreement, such a group is more likely to see peace prevail compared with a rebel group on the outside of the deal. This is notable, since the results at the settlement level indicate that an all-inclusive-agreement does not make the signatories any more likely to stick to peace. The results here at the dyadic level thus add an important piece of information, by showing that it does make a difference whether the parties sign settlements or not.

In an effort to probe deeper into the mechanisms, I explore whether the exclusion of parties is affecting the signatories' commitment to peace. Given that the fourth and fifth implications focus specifically on the

signatories, the analysis is carried out on a sub-sample that consists of the signatory dyads. The fourth implication suggests that the signatories should not be any more likely to resort to violence if a deal excludes some of the parties. This is evaluated in Model 2, Table II, and the variable *exclusive-peace agreement* shows no statistically significant effect on the risk of the signatories engaging in post-settlement armed conflict. This is in line with the argument, as the signatories should have taken into account whether some actor was excluded from the agreement, and hence, it should not affect the signatories' commitment to peace.

The fifth and last implication takes this notion of exclusion one step further. Even if the signatories are faced with excluded parties that engage in conflict, we should not expect to see an increase in the risk of signatory violence. The variable *excluded-fight*, which captures whether there is one or more excluded groups that are engaged in conflict with the government, shows no statistically significant effect on the risk of signatories resorting to violence (Model 3, Table II). Hence, this finding is in line with the argument put forward. While the peace process might be considerably more difficult if there are violent challenges to a peace deal, the results suggest that the exclusion of parties only makes outside actors more likely to engage in violence, without necessarily increasing the risk that the signatory peace will fail.

Taken together, the findings from evaluating the five implications are well in line with the theoretical argument, suggesting that a deal that excludes some actors does not necessarily increase the risk that the signatories will engage in post-settlement violence. Indeed, a closer look at the data shows that there are several cases where the signatories stick to peace even when another warring party is left on the outside of the agreement. For example, the Philippine government in

²¹ The models at the dyadic level have also been conducted on a sub-sample of the conflicts with multiple actors (since two-party conflicts are all-inclusive by definition), but the results remain the same.

²² Since it is very rare that excluded parties are given anything in the peace agreement, I did not find it suitable to include the variable *power-sharing* in this model. When doing so, the variable *excluded* is no longer statistically significant but is still in the expected direction. I propose that the variable *power-sharing* is best thought of as an intervening variable, as it may explain why some signatories stick to peace and others not.

1996 reached a settlement with the MNLF (Moro National Liberation Front), and peace has prevailed in spite of continued violence involving the Abu Sayyaf, as well as the MILF (Moro Islamic Liberation Front).²³ Similarly, in Burundi, the signatories to the agreement reached in 2000, namely Frolina (National Liberation Front), Palipehutu (Party for the Liberation of the Hutu People), and CNDD (National Council for the Defence of Democracy), did not return to armed warfare in spite of the fact that CNDD-FDD (National Council for the Defence of Democracy–Forces for the Defence of Democracy) and Palipehutu-FNL (Party for the Liberation of the Hutu People–Forces for National Liberation) continued to fight. Notably, in both conflicts, the outside actors continued to fight, while the signatories remained committed to peace.

Hence, partial peace agreements may be one possible path to peace. This is not to suggest that partial agreements necessarily are better than all-inclusive deals. Indeed, the results show that excluded parties often continue to fight. This said, if some deals never materialize because it is too difficult to get all parties to agree, then a partial agreement could be an attractive option. After all, a deal that excludes some actor may be successful in terms of getting the signatories to stop fighting.²⁴ In order to ascertain whether a partial agreement is better than no agreement at all, it would be preferable to study all conflicts (i.e. also those conflicts where no settlement

has been reached) and compare the conflict behavior of the signatories to that of all non-signatories.²⁵ However, this lies outside the scope of this study. What can be done is to look at the duration of peace in substantive terms, by comparing the signatories with the non-signatories in this particular sample. Using the program Clarify, the expected duration of peace for signatories and non-signatories is estimated, holding all other variables at their median values (Tomz, Wittenberg & King, 2001).²⁶ The result shows that the difference in peace duration is quite substantial, in particular considering that the study only covers the post-Cold War period. The expected peace duration for a rebel group that has signed an agreement is approximately eight years, whereas the corresponding figure for a non-signatory is only about two years. In other words, being a signatory instead of a non-signatory adds another six years of peace.²⁷ Thus, these findings indicate that the signing of an agreement makes a substantial difference for peace.

The results were obtained while controlling for a number of factors, and some of these are shown to significantly affect the risk that peace fails following a settlement. The models focus on different dimensions of peace, and hence, it is not surprising that the results are not the same across all models. I will briefly present a few of the most notable findings. The results on the settlement level show that the intensity of the conflict is

²³ Armed conflict also came to involve the MNLF faction that emerged, whereas MNLF can be seen to have remained committed to peace.

²⁴ Occasionally, the signatories stop fighting some time before the agreement is signed. This could lead one to suspect that the decision to stop fighting led to the signing of the settlement, rather than the other way around. However, even if a group stops fighting before the signing of a deal, it may have done so in the anticipation of a future deal. The fact that the government agrees to sign an agreement and grants concessions suggests that the group continues to pose a military threat.

²⁵ For instance, there might be some kind of selection effect taking place. However, this is only a problem if there is some underlying factor that explains both why parties sign agreements and why they stick to peace.

²⁶ Note that Clarify cannot be used with a Cox model and does not allow for stratification. Instead, I employed a Weibull model without stratification, and the expected values should be seen as indicative only. Moreover, since peace duration is measured one year after the agreement, I have subtracted one year from the values given by Clarify.

²⁷ Looking only at the partial agreements, the expected peace duration is six years for the signatories, compared to only one and a half years for the non-signatories. Hence, there is still a substantive difference.

found to significantly affect the risk that peace fails. This is in line with previous findings showing that particularly deadly wars are more likely to see the conflict resume (Fortna, 2003). Furthermore, if agreements include some form of power-sharing, there is an increased chance of peace prevailing, which is in accordance with previous research (Hartzell & Hoddie, 2003). At the dyadic level, it is found that the risk that a dyad will engage in conflict increases if the conflict is fought over government rather than territory. Finally, concerning the role of third parties, the findings at the dyadic level indicate that non-UN peacekeeping forces are not very encouraging in terms of creating conditions for durable peace.

In addition to controlling for these factors identified in previous research, a number of alternative specifications and statistical tests were carried out.²⁸ To ascertain that no particular case is driving the results, I have identified outliers using deviance residuals and re-estimated the models without the outliers, but the results remain the same. Moreover, a potentially influential case is Chad, where many partial agreements have been signed. Thus, as a robustness check, I include a dummy variable for this conflict, but this

²⁸ I tested the assumption that the hazard is proportional by performing tests based on the scaled Schoenfeld residuals, and both covariate-specific and global tests were carried out. Some of the global and covariate-specific tests indicate violations of the assumption concerning the models at the dyadic level. To deal with this issue, I interacted one of the violated variables with $\log(t)$, added this new variable to the models, and then carried out these tests again (Box-Steffensmeier & Jones, 2004: 132–136). The tests then showed no signs of violations, and the results are very similar to the previous results. Hence, the original models are the ones presented in Table II. Furthermore, as an additional robustness check, I re-estimated the model using a Weibull model, but the main results do not change. The results are also robust to alternative specifications, such as clustering on conflict or country. In addition, since new parties may emerge, I used an alternative dependent variable at the settlement level that captures post-settlement violence involving a signatory, non-signatory, or a new party. The findings were basically the same as those obtained when examining the overall peace duration.

does not affect the results. Furthermore, in the models at the dyadic level, I tried some alternative measures of the variable *number of parties*, but the results also hold when using a dummy, capturing whether it was multi-party conflict or not, and when adding a square term of the linear measure in order to explore curvilinear effects. Moreover, the results remain the same when controlling for the type of political system and the level of economic development measured in the log of GDP per capita.²⁹ In sum, the various specifications show very similar results.

Conclusions

This article set out to evaluate the claim in previous research that all-inclusive peace agreements are more likely to provide durable peace than partial agreements that leave out one or more rebel groups. Applying insights from bargaining theory, it was proposed that the signatories should be able to anticipate the risk of violent challenges from outside actors and, hence, their commitment to peace will be unaffected. Indeed, whereas excluded parties are likely to continue to fight, the signatories to a deal should already have considered such a scenario. The findings of this study accord with these theoretical expectations. The results showed that whether an agreement leaves out some actor does not affect whether the signatories stick to peace, but partial agreements can reduce the overall prospects for peace. Also in line with my argument, the study showed that outside actors are more likely to engage in

²⁹ The data on GDP come from the National Accounts Main Aggregates Database (United Nations, 2006). The type of political system was examined using data from the Polity IV dataset, and the variable *polity* ranges from –10 to +10, where a higher score indicates a more democratic system. In order to control for a possible curvilinear relationship, I also used the variable *polity-squared*, measured as the square of the *polity* variable (Marshall & Jaggers, 2003).

post-settlement violence than the signatories. Importantly, the findings indicated that, even if parties are excluded and continue to fight, this does not affect the signatories' commitment to peace.

This study contributes to the scholarly literature in several ways. To begin with, by moving away from a characterization of civil war as involving only two parties and considering all rebel groups, this article contributes to the recent studies that, in various ways, attempt to take the empirical analysis one step further by disaggregating the study of civil war (e.g. Cunningham, 2006; Cunningham, Gleditsch & Salehyan, 2007; Nilsson, 2006; Svensson, 2007). Furthermore, by taking into account all rebel groups, it became possible to incorporate insights from case studies into the quantitative analysis, which facilitated an inquiry into the global patterns of inclusive peace agreements and durable peace. The finding that agreements that leave out some actor reduce the overall prospects for peace is in line with previous arguments, but, to the extent that scholars on this topic have suggested that all-inclusive deals may affect the signatories' commitment to peace, the results here suggest otherwise (e.g. Rubin, 2002). The analysis also shed some light on our understanding of spoilers (e.g. Downs & Stedman, 2002; Stedman, 1997). While spoiler attacks in various ways may influence a peace process, this study indicates that the exclusion of rebel groups from a settlement does not necessarily disrupt the peace among the signatories. This said, the exclusion of actors might play a role in specific cases and, in some instances, result in intensification of violence. Hence, more research on this topic is needed.

Furthermore, one implication of the argument that the warring parties are forward-looking is that some agreements never materialize if the parties deem the prospects for peace so bleak that they see no point in

signing a deal at all. Therefore, a fruitful avenue for future research is to study this prior stage in the bargaining process. Such an inquiry may also serve to address the issue of whether a partial agreement is better than no agreement at all. Related to this, it would be interesting to study whether there are certain types of groups that sign agreements and how this may influence the duration of peace.

The result that all-inclusive agreements do not affect the signatories' commitment to peace is perhaps less discouraging than it first appears. An important conclusion from the present study for policymakers is that it may be worthwhile for third parties to try to facilitate agreements even if it proves difficult or even impossible to bring all the parties to sign a deal. Indeed, the results demonstrate that, even when excluded rebel groups engage in conflict, this does not affect the signatories' commitment to peace. Hence, this study shows that partial peace is possible.
